Coarctation of Aorta.—Reifenstein and his associates review the necropsies in 104 cases of coarctation of the aorta. Although coarctation occasionally was compatible with long life, many died before or during their fortieth year of life, the average age at death being 35 years. The lesion was more common in males. Death was due to incidental causes in 26 per cent, rupture of the aorta (most commonly the ascending portion) in 23 per cent, bacterial endocarditis or aortitis in 22 per cent, congestive failure in 18 per cent and intracranial lesions (exclusive of embolism from bacterial endocarditis) in 11 per cent. Congestive failure was common, but almost all patients who died of this cause had additional cardiovascular burdens, chiefly chronic valvular disease. Bicuspid aortic valves were the commonest congenital anomaly associated with coarctation, being present particularly in cases of bacterial endocarditis. Dilatation of the aorta was common, especially in its ascending portion. The degree of coarctation appeared to be related to the extent of collateral arterial development and the frequency of antemortem diagnosis, which was 40 per cent in this series. The cardinal features of coarctation include hypertension in the upper extremities, lower blood pressure in the legs, collateral arterial anastomoses, the systolic murmur and cardiac hypertrophy. When resection of the area of coarctation with anastomosis of the cut ends of the aorta is not feasible, surgical treatment of the associated hypertension may be of value. Surgery affords the only possible cure of this condition.

Origin of Left Coronary Artery from Pulmonary Artery.—Kaunitz reports clinical and postmortem observations on 2 infants aged 3 and 6 months at death in which the left coronary artery arose from the pulmonary artery. No additional cardiac anomalies were present. In both cases there was excessive dilatation and hypertrophy of the left ventricle, with necrosis, fibrosis, calcification and dilated sinuses in the myocardium. There was musculoelastic thickening of the intima of some of the smaller arteries. Fibroelastic thickening of the endocardium of the left ventricle was present. It is felt that these changes are attributable to chronic anoxia of the portion of the heart supplied by the left coronary artery.

Cardiac Asystole in Normal Young Man.—Eichna and his co-workers report observations on a man aged 22 who had completed basic training and for the preceding four months had engaged in clerical duties. His performance on fitness tests indicated an average physical fitness. On Oct. 19, 1942 he performed the Harvard pack test, became exhausted after four minutes and ten seconds and developed orthostatic hypotension with syncope in the postexertional standing periods. On Oct. 29, 1942 he performed the test for the second time. He had had a mild cold for four days. After two minutes and thirty seconds of effort he was stopped because he began to lag behind the required pace of one step-up per two seconds. During the second erect period the systolic blood pressure fell steadily. The heart rate, instead of accelerating, slowed progressively. Signs of increasing discomfort and incipient syncope developed. After standing for two minutes and forty-five seconds of this period, the blood pressure was 100/90 and the heart rate 99 per minute; the man was in severe distress. Suddenly the heart rate slowed, and before he could be tilted flat he lost consciousness, collapsed and had a short clonic convulsion. After he became supine consciousness rapidly returned and with it apparently complete subjective recovery. Such an asystole raises the question whether sudden death during and after physical exertion may not be the result of a fatal vasovagal syncope.

Pulmonary Calcifications and Sensitivity to Histoplasmin.—Waring and Gregg made contact tests with tuberculin and roentgenograms on 494 children of school age in Charleston County, S. C. Among the children in whom the tuberculin reaction was negative 349 had a normal roentgenogram and 8 had pulmonary calcifications. Intradermal tests with histoplasmin could not be made on all the children, but of the 8 with pulmonary calcification and negative reactions to tuberculin each was given an intradermal injection of a 1 : 100 dilution of histoplasmin and simultaneously an intradermal test with 0.1 mg. of old tuberculin. Only 1 of those whose reaction had been negative to the contact test with tuberculin reacted positively when 0.1 mg. of old tuberculin was injected intradermally. This child also reacted positively to histoplasmin. All 5 who reacted positively to histoplasmin had either lived in or made prolonged visits in Kentucky, Tennessee, Alabama or Mississippi—all within the area of high incidence of sensitivity determined in the study of the U. S. Public Health Service.

Effect of Measles on Nephrotic Syndrome.—Blumberg and Cassady report observations on 5 patients with nephrosis in whom measles developed while they were hospitalized. Two of the 5 patients presented the picture of the nephrotic syndrome with edema, albuminuria, hypoproteinemia, hypoalbuminemia, hypercholesteremia and normal blood pressure, and 3 presented the same picture with a nephritic element, with azotemia and hematuria. In the 2 patients with the uncomplicated nephrotic syndrome the disease subsided. One of these was still well when seen ten months later, while the other relapsed after a remission of three and a half months. The remaining 3 patients experienced transient modification of their disease. Reports of 4 or 5 complete cures of nephrosis by infection with measles were found in the literature.

*Effect of Cigaret Smoking on Malnutrition and Digestion. A. E. Koehler, Elsie Hill and N. Marsh.—p. 208.

Cigaret Smoking in Malnutrition and Digestion.—Koehler and his associates studied the effect of cigaret smoking on the flow of digestive secretions. Smoking of three cigarets in succession did not significantly influence the rate of flow or the concentration of amylolytic, proteolytic and lipolytic enzymes of the duodenal secretions as obtained by transduodenal drainage. Thus, although excessive cigaret smoking may be a dominant factor in the prevention of weight gain in underweight subjects on an adequate dietary program, the adverse effect is not due to a diminution of the secretions of the pancreatic ferments. The excessive smokers who were underweight all manifested a certain indifference to foods frequently bordering on a mild anorexia. Cessation of smoking definitely improved the appetite in this group, and it is believed that improved appetite and increased food intake were the main cause of weight gain.

Auditory Deterioration in Airline Pilots.—Graebner presents a survey of the audiometric findings of a group of 449 airline pilots of various ages and of various air hours' experience. The pilot under survey was checked on chronological age in years of life and physiologic age in air hours flown. All tracings were made on one standardized audiometer in steps of 5 decibels to determine the threshold of sound perception in each ear over the tone range from 128 to 11,584 cycles per second. Graphs showing the results of the tests give the general impression of definite causal relation of professional aviation and auditory deterioration. Clinical experience suggests cochlear damage due to acoustic trauma. Normal function of the conductive apparatus is corroborated by tuning fork tests. Tinnitus was conspicuous by its absence. All findings suggest a functional deterioration rather than a disease process. Deterioration in important spectrums, such as range stations, fan markers and outer and inner markers, would create difficulties in making instrument approaches. The constant radio signal of range stations may cause auditory fatigue. Airline flight surgeons should determine the threshold of hearing in these spectrums and to that end the standard audiometer should be equipped with frequencies to cover these tones that are broadcast for the guidance of pilots in flight.

Infarct of Prostate.—Rogers reports 2 cases of infarct of the prostate. Infarct of a hypertrophied prostate may occur as a result of interference with the blood circulation. These vascular changes are most often the result of trauma from transurethral procedures. The symptoms of prostatic infarction are largely those of urinary obstruction which results from the swelling and increase in the volume of the gland. When healing takes place a certain amount of contraction occurs and the volume is decreased. As a result of this decrease in volume, obstructive symptoms may be less severe than before the infarct developed. This may account for some of the results following bizarre methods of treatment. Diagnosis of infarction may be made clinically or cystoscopically on occasion, but it usually depends on examination of the tissue removed at operation or necropsy. Correct diagnosis is important in order to differentiate the condition from carcinoma.

Carcinoma of Prostate in Identical Twins.—Fister reports the histories of twins who developed simultaneously adenocarcinoma of the prostate. Both had hypertension, obesity and diabetes. Transurethral prostatic resection was performed in each case at an interval of one month. Diethylstilbestrol therapy and orchiectomy were carried out in case 1, in which the cancer was apparently more advanced and symptoms of metastasis evident. This treatment was followed by reduction in size and hardness of the gland, decrease in pain and improvement in general health. Both twins are doing fairly well two years after resection. Future study of these patients will be of interest, as one has been castrated and the other has not.

Streptomycin in Urinary Tract Infections.—Kleinman and his associates report experiences with streptomycin therapy of nonvenereal urinary tract infections in 18 patients. Seventeen of the 18 had neurogenic bladders resulting from spinal cord injuries. A preliminary study of the bacterial flora cultured from the infected urinary tracts of 42 similar patients showed that the organisms occurred in the following order of frequency: Streptococcus nonhemolyticus, Bacillus proteus, Aerobacter aerogenes, Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Staphylococcus aureus and Streptococcus hemolyticus. All but the last 2 organisms are known to be resistant to penicillin and the sulfonamides. With dosages of 3,000,000 units of streptomycin a day for three days prompt sterilization of the urine was obtained, but only temporarily. With dosages of 1,200,000 units a day for three days the results were generally poor, except in the 1 patient who did not have a neurogenic bladder. The failure of streptomycin therapy of urinary tract infections in paraplegic patients with neurogenic bladders is attributed to the presence of one or more of the following conditions: persistent suprapubic fistulas, urinary calculi, residual urine or repeated catheterization, or inadequate dosage.

Chronic Pancreatitis, with Extension to Wall of Stomach.—p. 371.

Protein Nutrition with Digest of Liver Protein.—Lewis and her associates administered a partial enzymatic digest of liver protein as a food supplement to 65 patients. The digest contained 60 per cent protein in addition to relatively large quantities of vitamin B complex. The taste of the liver protein digest is somewhat disagreeable. A laxative effect was observed in some patients. The liver protein digest supported positive nitrogen balance or nitrogen equilibrium when given as the chief source of protein to 5 normal subjects and 4 malnourished patients. Plasma protein regeneration was demonstrated in 1 patient with nephrosis and in 1 with uncomplicated malnutrition, as well as in several patients with cirrhosis of the liver. The results of the treatment of 19 patients with portal cirrhosis was at least as satisfactory as those attained with other means of supplying the many nutrients that have recently been advocated for the treatment of this disease. The recovery of 5 patients with infectious hepatitis progressed satisfactorily. The liver protein digest proved to be an adequate protein supplement for 4 of 5 patients with severe thermal burns. The digest was given to 3 patients with peptic ulcers, with excellent results. It proved satisfactory in 3 patients with alcoholic peripheral neuritis. Great improvement was observed in 10 of 14 patients with malnourishment of various causes.

Antidotal Effects of BAL Against Therapeutic Arsenicals.—Stocken and his associates say that BAL has been tested as an antidote to the toxic action of mapharside, neoarsphenamine and arsphenamine. Through use of the pyruvate oxidase system of brain it has been shown that BAL can protect effectively against these three arsenicals and can also bring about a significant degree of reactivation of the already poisoned enzyme system. BAL is also effective in bringing about the survival of rats after the injection of lethal doses of mapharside or neoarsphenamine.

Cultivation of Etiologic Agent of Rabies in Vitro.—Veeraraghavan describes a simple medium which contains steamed sheep brain extract, sheep serum, aminoacetic acid (glycine) and peptone, which he used for the cultivation of rabies fixed virus in vitro. He found that with this medium it is possible to obtain at least five times the maximum concentration of virus obtained in the brains of infected sheep used in the manufacture of antirabic vaccine. Cultivation under strict anaerobic conditions gives better results than under aerobic conditions. The successful cultivation of the etiologic agent of rabies in a cell free medium proves that it is not a virus in the accepted sense of the term. Protection afforded by culture vaccine the virus content of which is adjusted to be equal to that of 5 per cent phenol vaccine compares favorably with that obtained with phenol vaccine.

Antirabic Immunization with Culture Vaccine.—Veeraraghavan stresses that his culture vaccine is superior to Semple's 5 per cent vaccine, which is used in India. The virus content of the vaccine can be accurately determined. It is 100 times as high as that present in 5 per cent phenol vaccine. It is free from gross nerve tissue. It is apparently free from toxic effects. Assuming that five times the quantity of virus ordinarily used in treatment with phenol vaccine is necessary for producing adequate immunity in man, it should be possible to give with 7 cc. of undiluted culture vaccine five times the virus content present in 140 cc. of phenol vaccine.

*Intrapericardial Penicillin. H. Franco.—p. 41.

Intrapericardial Penicillin.—A man aged 22 presented symptoms of pericardial effusion complicating influenza. Sulfanilamide and intramuscular injections of penicillin were without effect. Aspiration of pus and instillation of 50,000 units of penicillin in isotonic solution of sodium chloride into the pericardial sac performed four times at intervals of four days resulted in recovery. Klebsiella pneumoniae was identified in cultures of the pus. The organism could no longer be demonstrated in the pus after the second injection. Attention is directed to the fact that the bacillus was regarded as being resistant to penicillin, whereas the results in this case suggest that it is not.

*Castration in Treatment of Psychopathic Criminals. F. Hartsuiker.—p. 263.

Measles Pneumonia in Children Returning from India.—Lubsen and Verlinde review observations on children who developed pneumonia following measles contracted while on board ship returning from India. In 1 child on whom a postmortem was done seventeen days after the onset of the measles exanthem laryngitis, tracheitis and mucopurulent bronchitis were found together with an extensive bronchopneumonia. One of the authors was able to isolate from the lungs a virus that was almost certainly identical with a virus isolated from the blood of a measles patient on the first day of the exanthem. In the lungs Hemophilus influenzae and anhemolytic streptococci were also found. This explains the fact that these patients did not react favorably to penicillin and sulfathiazole.

Castration in Treatment of Psychopathic Criminals.—Hartsuiker says that since 1938 certain groups of sexual delinquents have been treated in the Netherlands by removal of the testes. The Justice Department of the Netherlands recommends that the operation be performed only on men who are not less than 25 years old and only with the consent of the patient. The author reviews observations on 88 criminals who were so treated and says that the results so far have been generally favorable. He discusses the physical and psychic consequences of castration and demonstrates with the aid of a case history that libido and potency are not linked to the secretion of the testicular hormone.

Porcelain Silicosis.—Eskildsen and Møller say that an investigation was begun in 1941 to control the efficacy of the improvements in the dust prophylaxis among Danish porcelain workers introduced in 1933. Observations were made on 39 young workers, all of whom were subjected to two x-ray examinations. The diagnosis became certain only during the second stage of silicosis, the peribronchial perivascular type, with gradual increase of the interstitial extension of the fibrosis and comparatively rare combination with nodular changes. The incipient stage was discovered at the first x-ray examination in 15 cases. In 6 of these the diagnosis of silicosis could not be maintained with certainty at the second, although 5 of them had continued their work in the porcelain industry for as long as twelve years.

Book Notices

Injuries of the Knee Joint. By I. S. Smillie, O.B.E., M.B., F.R.C.S., Surgeon-in-Charge, Orthopaedic Hospital, Larbert, Stirlingshire (Scottish E. M. S.). Cloth. Price, $9. Pp. 320, with 350 illustrations. William Wood and Company, Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This is one of the best books on injuries of the knee that has been published. The author has had vast experience, having treated "2,235 cases in five years in the hospital" and "in addition 2,700 internal derangements in service personnel, mining and industrial workers were referred for consultation during the same period." This work was done in the Orthopedic Unit of the Base Hospital set up by the Department of Health for Scotland in 1940.

The book starts out with a comparative anatomy description of knee action and an explanation of quadriceps insufficiency which the author ascribes in part as due to the late acquisition in man's evolution from a quadruped to the erect posture. When injury occurs the lately acquired function of supporting orthograde posture easily disappears. The quadriceps and especially the vastus medialis wastes quickly. This inhibition should be overcome by early active non-weight bearing exercises which do not produce movement of the joint. Later graded exercises, even with weights, should be used. The book goes on to deal with synovitis, hemarthrosis and the necessity of early aspiration in case of swelling of the joint. The next four chapters take up in detail the surgical anatomy and physiology of the menisci and mechanism of their injuries, surgical pathology, clinical features of their internal derangment and the treatment, after-treatment and complications of injuries to the menisci. The necessity for complete removal of an injured meniscus is emphasized. The author illustrates special knives with a cutting edge on the end. The knives should be kept sharp. An elaborate system of postoperative treatment with gradually increasing exercise should return the patient to A I category in rarely less than twelve weeks. This seems like a safe opinion.

Complications of pain; hemarthrosis necessitating aspiration; sepsis, usually a result of faulty aseptic technic, treated by sulfonamide drugs—the author not having had opportunity to test penicillin but which since has proved efficacious elsewhere; aspiration done and opening of joints widely avoided if possible; persistent effusion; neuroma of infrapatellar branch of saphenous nerve, excised. Injuries of the ligaments are diagnosed and treated conservatively or by operation. The latter shows several technics, but the end results are not guaranteed, and no conclusion has been reached as yet about them. Injuries of the extensor apparatus are dealt with. In fractured patella the smaller fragment may be removed. Fractures of the tibia and femur require careful fixation of fragments in anatomic position, often requiring operation. The last chapters deal with foreign bodies, wounds of the joints and finally the stiff joint requiring prophylactic early motion and at worst manipulation under anesthesia or operative treatment. The book is well prepared and edited. The excellent illustrations add much to its value, and make this volume an unusually meritorious contribution.

Cardiovascular Diseases. By David Scherf, M.D., F.A.C.P., Associate Professor of Medicine, New York Medical College, Flower and Fifth Avenue Hospitals, New York, and Linn J. Boyd, M.D., F.A.C.P., Professor of Medicine, New York Medical College, Flower and Fifth Avenue Hospitals. [Based on previous editions of book of same title.] Fabrikoid. Price, $10. Pp. 478, with 56 illustrations. J. B. Lippincott Co., 227 S. Sixth St., Philadelphia 5, 1947.

This is in reality a new edition which has been completely rewritten to make the coverage of cardiovascular diseases more complete. The topic of rheumatic fever has been greatly expanded. Newer advances in diagnosis and in treatment are introduced. The material covered lives up to the title in that the authors are not concerned only with diseases of the heart but give proper emphasis to the diseases of the blood vessels.

In dealing with the clinical aspects of cardiovascular diseases the authors are at their best, although at times the old tradition of the Viennese school in which the senior author grew up is given undue prominence. There is also too much concern with the problem of priority. However, the American reader will find adequate coverage and proper reference to the earlier European work which might otherwise be forgotten. This book shares with many other clinical textbooks, and perhaps more so than others, the tendency to explain mechanisms on physiologic grounds which are often superficial and contradictory to the present knowledge of normal and pathologic physiology. In this regard the volume is weak. It is regrettable also that picturesque language is at times introduced which is out of place with the more sober general context.

This book can be recommended for the many practical hints which it contains, for its summary of European work, for its refreshingly different handling of this subject and for its proper balance in dealing with the various aspects of cardiovascular diseases. The format and illustrations are on the whole excellent, although on occasion imperfections of the type appear.

Outlines of Internal Medicine. Parts I-V. Edited by C. J. Watson, M.D., Head, Department of Medicine, University of Minnesota, Minneapolis. Fifth edition. Paper. Looseleaf. Price, $9 per set. Pp. 161; 108; 112; 61; 95, with 12 illustrations. W. C. Brown Co., 973 Main St., Dubuque, Iowa, 1946.

These outlines, prepared in five parts, present to the student a succinct fund of information relative to the bacteriology, physiology, diagnosis and treatment of disease. Part I includes infectious diseases, allergies and arthritis. Part II covers diseases of the blood, liver and biliary tract, pancreas and intestinal tract. Part III deals with the heart. Part IV is concerned with deficiency and metabolic diseases, while part V is devoted entirely to clinical chemistry and microscopy. In all sections the material is carefully compiled and well indexed, and the contents are largely confined to noncontroversial information. There is included enough history to interest the student, and a well selected bibliography follows each chapter. The material as organized should stimulate the student to pursue on his own a program of medical instruction which is much more valuable than attempting to cover the material in a series of didactic lectures with page assignments in a standard textbook. In the bibliography are included references to many original articles dealing with the subject under consideration. All in all, it is a most satisfactory compilation of essential information and is recommended to all students of medicine, including those who have graduated.

What Is Heart Disease: A Handbook for the Heart Patient. By William Hyatt Gordon, M.D., F.A.C.P., Head of Medical Section, Lubbock Memorial Hospital and Clinic, Lubbock, Texas. Cloth. Price, $2.50. Pp. 114, with 10 illustrations. Grune & Stratton, 381 4th Ave., New York 16, 1946.

This small book is written at a mutual intellectual level for the physician and his patient who is afflicted with heart disease. Most busy physicians are unable to afford sufficient time to outline the reasons for medical management of a particular cardiac problem to the complete satisfaction of the patient. This the author attempts to do by first explaining that heart disease does not signify a single rapidly fatal process but that heart disease varies greatly in its gravity, usually has a chronic course and need not be cause for invalidism. The book attempts to aid the patient by first describing the anatomy and the physiology of the normal heart and its amazing ability to endure added effort and handicaps.

The author then discusses the pathology and the abnormal physiology of diseases of coronary vessels, disorders of the heart valves, diseases of the heart muscle and abnormal heart beats. This is followed by a section on the treatment of heart disease. Many incorrect ideas and much unfortunate knowledge possessed by the average person are exposed and corrected throughout the entire book.

A splendid addition is the last chapter, entitled "Symptoms Erroneously Thought to Indicate Heart Disease." Functional disorders frequently force apprehensive patients to go from physician to physician in an attempt to obtain a diagnosis of organic heart disease. The author advises them to consult a competent physician and to accept his advice, for "there is nothing more tragic than needless invalidism caused by a nonexistent disease."

This book may be considered a good contribution for the layman. It is written in simple, understandable language, but because of its brevity questions will be left in the minds of many persons who read it as a guide for a specific cardiac disorder.

On the Morphology of Blood and Bone-Marrow in Thyrotoxicosis. By O. Biström Inaugural Dissertation, II Surgical University Clinic, Helsingfors. Acta chirurgica Scandinavica, Vol. XCIV. Supplementum 114. Paper. Pp. 188. Helsingfors, 1946.

The author reviews the earlier literature and then reports his own investigation on the peripheral blood and bone marrow findings in thyrotoxicosis. He obtained the bone marrow by sternal aspiration. A control group of 24 surgical patients were studied, excluding those with diseases which might influence the blood or bone marrow characteristically. Twenty-six patients with nontoxic goiter were next studied to compare with 33 patients with thyrotoxicosis. The immediate postoperative findings in the nontoxic group of cases were a proportionate decrease in erythrocytes and hemoglobin and a polymorphonuclear leukocytosis in the peripheral blood. There was often a thrombocytosis and reticulocytosis also. The white cells of the marrow showed little alteration, while the decrease in normoblasts was the most regular and conspicuous feature. Fifty per cent of the patients examined at follow-up examination three months later showed improvement in the red blood cell values but not quite to normal, a distinct leukopenia due to a decreased number of granulocytes and an improvement in erythropoiesis in the marrow.

Comparison of the peripheral blood and marrow of patients of varying degrees of thyrotoxicosis offered little information. There was a tendency toward macrocytosis. Low values for leukocytes were found more commonly in this group than in the controls and some showed slight leukopenia. Granulocytes were low in relative and absolute values, while the lymphocytes were often increased. A higher degree of lymphocytosis was found in the more severe cases of thyrotoxicosis. The sternal marrow showed a shift of the granulocytes to the left. No increase in lymphocytes in the marrow was revealed when compared with the control cases. The changes in the marrow and peripheral blood were inconstant, and the changes enumerated were characterized as tendencies. The patients treated preoperatively with iodine showed an increase in leukocytes, mainly granulocytes, in the majority of cases. The lymphocyte change was equivocal. The shift of granulocytes to the left in the marrow receded on iodine therapy, depending on the duration of the therapy, but did not reach the control values.

Changes observed in 5 patients treated preoperatively with thiouracil were improvement in red blood cell counts and hemoglobin where they were formerly reduced; decreased white blood cell count due mainly to a decrease in granulocytes, shift of the granulocytes in the bone marrow to the right where formerly there was a shift to the left, and an increase in adult forms of nucleated red cells. In five to eight days postoperatively a decrease in red cells and hemoglobin occurred similar to the immediate postoperative findings in the nontoxic group. Increase in granulocytes was more obvious than in the nontoxic group. The findings in the bone marrow were comparable to those in the nontoxic group and consisted mainly in increased erythropoiesis. In the three month postoperative follow-up the erythrocyte and hemoglobin values did not reach the preoperative values; low values were found for the leukocytes in one third of the cases; cases which previously showed an absolute lymphocytosis were reduced to relative values; the granulocytes showed no constant pattern. The bone marrow showed a moderate shift to the right. There was less active erythropoiesis at normoblastic levels than before treatment.

In his study of the correlation of lymphocytosis in the blood and lymphocytic infiltrates in the surgically removed thyroid glands, the author constantly found that lymphocytic infiltration in the goiter tissue occurred, especially in the presence of high grade thyrotoxicosis, where an absolute lymphocytosis occurred in the peripheral blood.

The author concluded that patients with nontoxic goiter do not show any characteristic changes. In thyrotoxicosis the bone marrow shows evidence of a slight maturation arrest, possibly in response to the increased metabolic rate. When the metabolic rate was reduced by iodine, thiouracil or surgery, the shift of the bone marrow elements to the left was decreased and this is simultaneously reflected in the peripheral blood. The danger of granulocytopenia after thiouracil is stressed especially in thyrotoxic states in which the myeloid tissue is already disturbed. While the author was not able to account for the lymphocytosis in the peripheral blood in thyrotoxic states, he was inclined to explain it on the basis of lymphocytic infiltration of the thyroid gland. The variation of the changes in the blood or bone marrow was not considered to be of great diagnostic or prognostic importance in thyrotoxicosis.

In this thorough and objective survey on peripheral blood and bone marrow findings in thyrotoxicosis, it is unfortunate that the recent literature was not available because of wartime conditions. The publications of Renzi and Lenzi in 1939 and the article of Robert Jones in 1940 should have been available, however. Jones found a constant myeloid hyperplasia of the aspirated sternal bone marrow in hyperthyroidism that was not reflected in the peripheral blood. Nevertheless the material presented in this monograph was well controlled and adequately studied. The author's conservatism in drawing conclusions concerning the diagnostic and prognostic value of peripheral blood and bone marrow findings is in keeping with sound scientific thinking. The monograph is a definite contribution to the field of hematology and internal medicine and represents the most comprehensive and controlled study in this field.

Diagnostic électrocardiographique. Par André Jouve, Jacques Senez, chef de Clinique à la Faculté de médecine de Marseille, et Jean Pierron, chef de Clinique à la Faculté de médecine de Marseille, Marseille. Préface du Professeur Ch. Laubry. Paper. Price, 860 francs. Pp. 362, with 217 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris, 6e, 1946.

This textbook on electrocardiography is written with considerable knowledge of the entire subject, and the authors are familiar with the American literature and frequently refer to it. The book is divided into four parts, covering (1) the theoretical basis and technic, (2) the normal electrocardiogram, (3) the pathologic electrocardiogram and (4) the clinical application of electrocardiography. The classification of abnormal electrocardiograms is unorthodox and therefore confusing to beginners in this country, who will follow the American tradition. The diagnostic importance of chest leads is stressed. However, a polarity is used the reverse of that now universally accepted in English speaking countries following the recommendation of the official heart associations of Great Britain and America. It is to be hoped that the French Société de Cardiologie will also adopt the newer method of recording chest leads, so that the nomenclature will become uniform.

Most of the illustrations are well reproduced. It is regrettable that in a book which gives so much detailed information no illustrations are available to demonstrate the effect of acute cor pulmonale and of digitalis on the electrocardiographic contour. It is regrettable also that the effects of excess digitalis on heart rhythm are not illustrated. Some discussion of the effects of low calcium and high potassium in the blood should have been included. No illustrations of the effects of digitalis and of quinidine on auricular fibrillation and flutter are shown. The electrocardiographic modifications reflecting left ventricular preponderance or predominance, the latter apparently being the French term used for "strain," are discussed together with deviation of the electrical axis; no mention is made of the pattern of left heart strain occurring in the absence of abnormal deviation of the electrical axis.

A number of errors in interpreting arrhythmias appear. For example, no distinction is made between the normal refractory phase giving rise to auriculoventricular dissociation and the abnormal depression of auriculoventricular conduction giving rise to auriculoventricular block. Accordingly the authors fail to see how the classic concept of auriculoventricular conduction—in contrast to that of the French school led by Geraudél—can explain the occurrence of ventricular capture in auriculoventricular dissociation. A rather confused definition is given of interference—dissociation, misquoting both Mobitz, and Wenckebach and Winterberg. The disturbances termed "isorhythmic dissociation" and "sinus bradycardia with permanent idioventricular rhythm" do not necessarily represent definite entities and are therefore unnecessary.

This textbook offers a new classification of the disturbances of impulse formation and impulse conduction which may be interesting to the advanced student but it can only be confusing to the beginner. The American reader will welcome the well chosen references to the more recent French literature on electrocardiography.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SMALLPOX VACCINATION

To the Editor:—Kindly give me the following information concerning smallpox vaccination in an adult: 1. Indications or contraindications in a woman who is within (*a*) the first four weeks of pregnancy, (*b*) first three months of pregnancy, (*c*) last month of pregnancy and (*d*) the puerperal stage. 2. Should a husband who is being revaccinated consider impregnating his wife at this time? If contraindicated, how long should he wait?

M.D., New York.

Answer.—1. If there is a history of exposure to smallpox there is no contraindication to vaccination. (*a, b, c* and *d*) The present consensus is that vaccination of a mother exposed to smallpox at any stage of pregnancy is not contraindicated.

2. There is no objection to a husband being vaccinated at any time.

In at least one large contagious disease hospital it has been customary for a period of thirty years to vaccinate all patients admitted who show no evidence of a successful vaccination against smallpox. There has never been any serious complication from such a procedure, regardless of the age of the patient or the disease from which the patient suffered at the time of vaccination. However, if vaccination is not imperative because of exposure to smallpox, it is ill advised to perform this operation on individuals suffering from either acute or chronic eczema or various forms of dermatitis, on account of the danger of multiple accidental vaccinations occurring.

DIAGNOSIS OF POLYCYTHEMIA

To the Editor:—A man aged 35 has had chronic throbbing headaches for ten to twelve months. Six years ago, while working as a tire recapper, he had similar headaches. Four years ago while working in the galvanizing plant of a shipyard he was treated for acute zinc poisoning and was forced to give up such work. He is now back at his trade of tire recapper. In the course of his work he is exposed to both rubber dust and fumes of rubber solvent (supposedly petroleum benzin). Examination is negative except for a manifest midphase cardiac murmur over the pulmonic area. The lungs are normal on physical examination. Erythrocytes number 5,360,000. Hemoglobin is 16.2 Gm. per hundred cubic centimeters. There is a moderate but decided shift of the granulocytes to the left. The sedimentation rate is slightly increased in the final phase. The definite but moderate degree of polycythemia is not accompanied by the dusky redness seen in the primary type of the disease. Differential diagnosis involves the problem of secondary stimulation of the blood forming organs by anoxemia due to occupational hazards, congenital heart disease and primary polycythemia vera. What is rubber solvent and will it act as a poison to the bone marrow? Will rubber dust produce a pneumonoconiosis or otherwise interfere sufficiently with the pulmonary circulation to effect a relative anoxemia? Please discuss the differential diagnosis of this case, with particular reference to the etiologic factors involved.

Zaven M. Seron, M.D., Sebring, Fla.

Answer.—The headache and polycythemia strongly suggest repeated low grade exposure to carbon monoxide. There may not be chronic carbon monoxide poisoning, but there may be chronic exposure to that gas. Leaky gas appliances at home or at work may account for the two manifestations mentioned but not for certain others coexisting. The earlier zinc poisoning is probably without consequence at the present time. Acute zinc poisoning (there is no chronic form) is due to the inhalation of freshly flocculated zinc oxide fume and in galvanizing commonly arises only when the metal is overheated. This condition is one of the "metal fume fevers." It is characterized by severe chilling, usually at night after exposure during the previous work period, by great thirst and by malaise. There is a twelve to twenty-four hour course, with full recovery. Tolerance is readily developed and readily lost. Rubber dust will not produce a demonstrable pneumonoconiosis, but possibly rubber or some of its adjuvants may be allergenic. The features described scarcely suggest sensitivity. At this time some solvents are mislabeled or at least do not represent full content of the label designation. Petroleum benzin is naphtha but might possess a certain content of benzene. If this is present it is unlikely to produce a polycythemia. The percentage of carbon monoxide hemoglobin in the patient's blood should be determined. If significant the exposure should be located. Otherwise the condition probably is not related to work.

PROPHYLAXIS OF SUBACUTE BACTERIAL ENDOCARDITIS

To the Editor:—What is the best procedure for the prevention of subacute bacterial endocarditis following dental extractions or similar possible precipitating factors in cases of rheumatic valvular heart disease? What is the dosage of penicillin and/or sulfonamides and the duration of treatment in such cases?

M.D., Connecticut.

Answer.—Opinion is not unanimous concerning the drugs or doses to be used as prophylactic procedures in patients with acquired or congenital cardiac lesions who have teeth extracted. Since penicillin does not provoke serious toxic manifestations, this antibiotic probably has first choice. Two to three hours before extraction one could give intramuscularly 300,000 units of penicillin suspended in peanut oil and beeswax. This dose could be repeated daily for two to three days following the extraction. Another method would be to administer tablets of penicillin orally. An hour or two before the extraction 50,000 units may be ingested, preferably with the stomach empty of food. Then for two to three days, 50,000 units may be taken four times a day. One dose could be given before each of three meals and one in the evening. If a sulfonamide is to be used, one must ascertain whether or not the patient is sensitive to the drug. Either sulfadiazine or sulfamerazine may be employed. To determine whether the person is sensitive to the selected drug, one could give 0.5 Gm. orally and then wait a period of six hours before administering any further drug. Then about two hours before the contemplated extraction 2 Gm. of either sulfonamide may be given orally. For the following two to three days 1 Gm. should be administered every six hours. The patient should be instructed to drink adequate amounts of fluid.

TREATMENT OF PREMENSTRUAL TENSION

To the Editor:—What is the present status of the use of anhydro-oxyprogesterone in the treatment of premenstrual tension?

Glenn W. Cosby, M.D., Miami, Okla.

Answer.—Premenstrual tension is probably due to the sudden rise of blood estrogens several days before the onset of menses (Freed, S. C.: The Treatment of Premenstrual Distress, The Journal, Feb. 17, 1945, p. 377). This rise in estrogens produces the various symptoms of premenstrual tension by causing an increase in the tissue fluid of the various organs; for example, swelling of the brain producing migraine, of the gastrointestinal tract, nausea, of the bladder, frequency of urination, or of the skin, nervousness and pruritus. Gilman, however, differs with these opinions and has claimed that progesterone is the inciting agent in the production of premenstrual tension (Gilman, Joseph: *J. Clin. Endocrinol.* **2**:157 [March] 1942). Nevertheless, these symptoms may be duplicated by administering rapidly absorbed estrogens to a patient in the menopause. The treatment of premenstrual tension is aimed at either neutralizing the action of estrogens by administering certain steroid hormones or relieving the water retention through the use of diuretics such as ammonium chloride. In some cases vitamin B complex may curb the increase in estrogens and thereby relieve the symptoms. Either progesterone or the androgens are effective in antagonizing the endogenous estrogens and thereby eliminating the symptoms, the androgens being more effective in this regard than progesterone. Anhydro-oxyprogesterone should theoretically produce a similar effect, since on an experimental basis it has an estrogen suppressing effect. However, clinically there is little evidence of this action, and in the experience of one investigator this treatment has been unsatisfactory.

POSTCOITAL HEADACHE AND LOSS OF MEMORY

To the Editor:—A man aged 30 complains that following coitus he experiences suboccipital headache and has difficulty in clear rationalization and memory for a period of twenty-four hours. He finds it difficult to remember and think clearly and becomes befuddled and uncertain of his ability to recall events or things. Can this be due to cerebral ischemia or cerebral congestion with straining on intercourse? This patient is not neurotic and I believe his story.

M.D., Texas.

Answer.—It is presumed that similar happenings have not been experienced by this man in any other stressful situation in which he might exert himself and overbreathe, or it would have been mentioned. It is also presumed that the recumbent posture was assumed in coitus and that the phenomena described followed each experience. It would be of interest to know the duration of coitus, the time elapsed between orgasm and onset of the first symptom, and whether the partner is usually the same person.

Syncope (fainting) and the syncope associated with hyperventilation may be dismissed from consideration, since symptoms lasting for twenty-four hours would not be apt to occur in these conditions.

Is it possible that the patient is suffering from disturbances of consciousness because of epilepsy? If so, the condition would most likely be psychomotor epilepsy, though it would be most unusual for this type of attack to follow sexual intercourse only. It is probably true that it is impossible to define the limits of psychomotor epilepsy, so that it may not be ruled out in this patient without more evidence.

The last sentence in the query probably contains the key to the solution of the patient's problem. "This patient is not neurotic and I believe his story." If there is anything to the association of ideas, and many studies have tested its validity, it may be inferred that the questioner seems to believe that neurosis and veracity are not likely associated; in other words, the person with a neurosis cannot be believed. If this is so, it must certainly disqualify him from deciding whether or not a group of symptoms are psychogenic.

Whether or not the symptoms described are on a psychogenic basis cannot be determined from the meager data supplied. However, the chances of this being the case are relatively good.

In an attempt to elucidate the cause of these symptoms the aid of a psychiatrist should be sought. Blood pressure readings in the recumbent, sitting and erect positions will probably be normal, as most likely will serial electroencephalograms done on several days during a week in which the patient notes these symptoms.

URTICARIA FOLLOWING PENICILLIN IN OIL AND WAX

To the Editor:—Several patients have developed severe generalized urticaria and pruritus following the administration of penicillin in oil and wax (Romansky formula). As penicillin itself is reported to be a remote cause of reaction, the question arises as to the allergenic properties of the vehicle in which it is administered. Has any method been developed to skin test or otherwise determine the sensitivity of a patient prior to the use of this formula? Willis P. Baker, M.D., Santa Ana, Calif.

Answer.—Evidence that the generalized urticarial eruption that follows the administration of penicillin in oil and wax (Romansky formula) is any more likely to occur with this preparation than with the use of penicillin in aqueous solution or in salt solution is not available. The evidence is good that the sensitization is due to the penicillin itself and not to the oil or wax, since patients who receive penicillin in aqueous solution after having been sensitized following the use of penicillin in oil and wax will react with an urticarial eruption. Extensive studies have been carried out to determine whether or not any pollen extracts are carried over in the beeswax, and all these studies have been negative.

HEMOGLOBIN

To the Editor:—1. In calculating hemoglobin values by the Sahli method, what effect does a wait of thirty minutes, one hour, two hours or a day have on the final reading after the blood and hydrochloric acid have been mixed? 2. What percentage of the hemoglobin molecule is protein?

Leon Paris, M.D., New York.

Answer.—The color of an acid hematin solution increases in intensity on standing. The formation of color is said to follow a rectangular, hyperbolic curve ending at infinity. Actual readings made at various time intervals on the same blood sample are as follows: 5 minutes, 12.7 Gm.; 30 minutes, 13.7 Gm.; one hour, 14.2 Gm.; two hours, 14.7 Gm.; twenty-four hours, 14.7 Gm. The importance of calibrating and reading the Sahli instrument after the acid hematin has stood for a fixed period is obvious. To save time, it is best to make the final reading at five or ten minutes.

Hemoglobin is a conjugated protein made up of heme (an iron-porphyrin complex) and globin (a water soluble basic protein) in the proportion of 1 part of heme to 26 parts of globin, and hence contains about 96.3 per cent of globin.

SILICONES AS SYRINGE LUBRICANT

To the Editor:—I have been using a small amount of "Dow-Corning Stopcock Grease" as a lubricant for my syringes used for giving parenteral medicaments. This is described commercially only as a "Silicone Lubricant." It functions well in giving a smooth action to the syringes. Are there any possible remote ill effects that might result, should some of this material find its way into the tissue?

Lyman C. Blair, M.D., Houston, Texas.

Answer.—The silicones represent such a new development in organic chemicals and are so highly numerous, at least potentially, that as yet real appraisal of toxicity is not available. Some may prove to be highly toxic and others wholly inert. Methyl silicate, an organic silicon compound, is extremely toxic, as determined under experimental conditions. "Silicone Lubricant," on the other hand, appears to be wholly inert. The only conceivable possibility of danger for use in syringes is related to the unlikely mishap from emboli.

TUMOR OF BREAST AND ESTROGEN THERAPY

To the Editor:—A woman aged 35 has noticed a slightly tender mass in her left breast for one week. Physical examination is normal except for a slightly tender, hard, easily movable mass about 1.5 cm. in diameter in the upper outer quadrant of her left breast about 4 cm. from the nipple. There is no retraction sign, dimpling or palpable axillary nodes. The remainder of the left breast and the right breast are normal. She is not pregnant, has never nursed, and there has not been any discharge from the nipple. Should this tumor be removed and sectioned? Could any benefit be expected from a course of estrogen therapy? Would estrogens be likely to cause malignant changes in a benign tumor or increase the malignancy of a carcinoma of the breast?

M.D., New Jersey.

Answer.—The tumor should be excised and a frozen section prepared in the operating room for microscopic study. There is no clear indication for estrogen therapy in this case. There is strong experimental evidence that under special conditions estrogens may stimulate and accelerate epithelial neoplasia in the breasts of animals. There have been some clinical observations supporting these findings, but they are not conclusive.

RADON OINTMENT FOR ARTHRITIS

To the Editor:—Please discuss the use of radon ointment for the treatment of arthritis. M.D., Michigan.

Answer.—Radon ointment has been used for the treatment of arthritis both here and in Europe for several years. The published reports sound encouraging. However, there has not been sufficient corroboration to evaluate with scientific accuracy the therapeutic effectiveness of this form of radiation therapy for arthritis.

METHOD OF HEMOGLOBIN DETERMINATION

To the Editor:—What method for hemoglobin estimation is recommended for a small hospital? Are grams per hundred cubic centimeters blood or percentages recommended for reporting hemoglobin values?

Isabelle N. Edwards, Greenport, N. Y.

Answer.—A photoelectric colorimeter is recommended for routine hemoglobin determinations. The types of apparatus available may be obtained from a laboratory supply house. The various methods and relative advantages of calibrating the photoelectric colorimeter are discussed by Wintrobe (Clinical Hematology, ed. 2, Philadelphia, Lea & Febiger 1946, p. 259).

Because of the variation in the hemoglobin value in normal persons and because of the variation with age and sex, the expression of hemoglobin in grams per hundred cubic centimeters of blood is preferred.

COMBINED USE OF PENICILLIN AND SULFONAMIDES

To the Editor:—Is there any contraindication to using penicillin along with any of the sulfonamides in the treatment of severe infections for which either would be indicated? Does one drug inhibit or nullify the action of the other? R. A. Yerg, M.D., Reno, Nev.

Answer.—There is no contraindication to the use of penicillin and sulfonamide in combination. Neither drug inhibits or nullifies the action of the other. It is always better medical practice to use only one of the drugs for the treatment of infections. Exceptions can be made in the treatment of mixed infections in which some organisms are sensitive to penicillin and others are sensitive to sulfonamides.

RECURRENT ERYSIPELAS OR FUNGOUS INFECTION

To the Editor:—In the April 5, 1947 issue of The Journal, page 1043, there is an answer to a question concerning recurrent erysipelas. It seems to me that this answer misses the two most likely possibilities, namely (1) that fissures between the toes caused by a fungous infection are serving as ports of entry for the streptococcus or (2) that the recurrent attacks are really not erysipelas but an erysipelas-like dermatophytid. In the July 10, 1943 issue of The Journal there was a similar question to which a detailed answer was given, which went into the possibilities mentioned and also gives the pertinent literature to date. Since then there has been a review of this subject by Waisman entitled "Recurrent Fixed Erysipelas-like Dermatophytids" (*Arch. Dermat. & Syph.* **53**: 10 [Jan.] 1946. I think these two possibilities should be considered, for if either plays a role, treatment which does not eradicate the epidermophytosis focus will be fruitless.

THE OBJECTIVES OF THE AMERICAN MEDICAL ASSOCIATION

President's Address

EDWARD L. BORTZ, M.D.
Philadelphia

In San Francisco one year ago the House of Delegates of the American Medical Association conferred the highest honor within its power on one of our nation's great medical statesmen, Dr. Olin West. It was a fitting climax in the life of a man who for more than twenty-five years had been a loyal servant to the medical profession. It is appropriate on the occasion of the Centennial Celebration to pay this word of tribute to that Southern gentleman who elevated his profession, served his nation and enriched his fellow man.

The American Medical Association is highly honored to have as its guests so many distinguished men from other nations of the world. Medical science extends beyond national frontiers. A discovery of importance in one nation ultimately becomes the property of all. The World Medical Association in the field of health is developing a program to facilitate the spread of medical knowledge to all parts of the world. The American Medical Association is cooperating in the program for extending the benefits of science beyond the frontiers of its native land.

THE FIRST MEETING

In Philadelphia in May 1847 a group of doctors stimulated by Nathan Smith Davis drew up plans for a national medical organization. Physicians with forward vision early recognized the need for stabilization in the training of doctors. The first objective for the new organization was a uniform and elevated standard of training leading to the degree of M.D. to be adopted by all the medical schools in the United States. Two hundred and fifty delegates representing some forty medical societies and twenty-eight medical colleges from twenty-two states and the District of Columbia attended the first meeting. Dr. Nathaniel Chapman, a Philadelphian, was elected the first President.

Medical science has progressed further in the last one hundred years than in the previous twenty centuries. Comparison of the medical training in 1847 with the highly organized system of medical education in 1947 indicates the long road which medicine has traveled. The first objective of the American Medical Association through the entire century has been a determined drive for a high standard of training.

At one time one hundred and sixty-five medical colleges in our country offered courses in medicine. Some schools admitted students directly from high school; others accepted young men with an elementary education. The training was for the most part sketchy.

Standardization on a high plane has resulted in an educational program for the development of doctors who are well instructed in the scientific treatment and understanding of disease.

Medical education has benefited greatly by the work of the Association of American Medical Colleges, the National Medical Examining Board, the Federation of State Licensing Boards and the Carnegie Foundation. Special credit is due Abraham Flexner and Nathan P. Colwell of the Council on Medical Education and Hospitals of the American Medical Association, who surveyed the medical schools of the nation soon after the turn of the century and made far reaching recommendations.

1897—THE HALF CENTURY MARK

In 1897 the really big news as carried in the history of this Association was the celebration of the Semi-Centennial in Philadelphia. A world famous surgeon was President, Dr. Nicholas Senn of Chicago. Four of the original founders were still alive: Drs. N. S. Davis of Chicago, Alfred Stille of Philadelphia, J. B. Johnson of St. Louis and D. F. Atwater of Massachusetts. Dr. Senn commented on the advancement of medical education, the improvement of American medical literature, the scientific work of the Association and the development of THE JOURNAL. He commented on the steady growth of the Association and praised the membership of 9,000, predicting that on the occasion of its hundredth anniversary the membership might increase to 75,000 or even 100,000. His estimates of success were sound: the membership of the Association now totals over 131,000 active members. Dr. Senn predicted that inventions and discoveries beyond the conception of his day would be reviewed by the hundredth President of the American Medical Association. The distinguished Senn looked for the growth of medicine and surgery into exact sciences and predicted that organized medicine would contribute liberally toward this end. His vision has proved correct. The dramatic triumphs in the field of public health, sanitation, and preventive and curative medicine have occurred with increasing rapidity as the exact methods of science have displaced empiricism and theory.

CHARLATANS AND PATENT MEDICINES

A review of the history of the Association which has appeared in THE JOURNAL during the past six months from the pen of its talented Editor describes the lively

---

President's address before the American Medical Association at the Ninety-Sixth Annual Session, Atlantic City, June 10, 1947.

interest which the Association has always taken in running down pernicious nostrums and worthless patent medicines for which the public each year squanders millions, and the investigation of dangerous quacks who prey on the gullibility of the public, offering high hope of sure cure for the sole reason of financial gain. These busybodies might be ignored were it not for the cruelty inherent in their methods.

An energetic campaign of education of the public is making it increasingly difficult for charlatans to practice their nefarious trade.

The code of ethics which governs the practice of medicine endeavors to protect an uninformed public against the claims of the charlatan. It states that "it is unprofessional to promise radical cures; to boast of cures and secret methods of treatment and remedies; to exhibit certificates of skill or success in the treatment of disease, or to employ any methods to gain the attention of the public for the purpose of obtaining patients."

When a reputable physician is in doubt he promptly requests consultation. The sole aim of such consultation is the benefit to be derived by the patient.

MEDICAL RESEARCH

Spectacular advances have taken place since the turn of the century in various fields of science. Medicine is not slow to investigate each new discovery in the hope of uncovering some valuable lead for the control of disease. Ever since its inception the American Medical Association has established inducements of various kinds to encourage medical research. Grants are awarded from year to year, special studies are fostered, and every encouragement is given to the utilization of the vast resources of the Association, which are made available for research in all fields of pure science and the medical specialties. Medicine in truth is a branch of biology; today medicine looks to the fields of pure science, physics, chemistry, botany, general biology and other branches of science for assistance in charting new paths in the control of disease and the improvement of public health. More than $1,000,000 has been contributed by the American Medical Association for fundamental investigations; from time to time further assistance is being made available as opportunities arise.

PUBLIC EDUCATION

Early in the development of the American Medical Association doctors were urged to take an interest in informing the public of the affairs of medicine and how they affected the public weal. Benjamin Rush, a Philadelphian and a leader in medicine at the time of the American Revolution, urged a campaign for the education of the public. Almost continually since the creation of the Association interest in public education on health matters has been one of its activities. Lectures and campaigns with reference to the protection of vision, the control of venereal disease, the importance of early recognition of cancer and the desirability for universal vaccination have been fostered. In recent years the public health magazine *Hygeia* has been published; its circulation runs into the hundreds of thousands. The people of this nation write over half a million letters a year to the Association headquarters to inquire concerning various aspects of health problems. Today the nation looks to the Association for authoritative information.

PUBLIC HEALTH ACTIVITIES

Early in the affairs of the American Medical Association the members urged the formation of State Health Departments for the purpose of developing public health facilities throughout the entire nation. The Association recommended the creation of a United States Public Health Service. Throughout its entire career organized medicine has urged governmental bodies to utilize all proved scientific measures for the protection of public health. All the resources of the Association are at the command of the national and state departments of health for the promotion of research, the education of the public, the support of campaigns for the study and control of cancer, heart disease, tuberculosis, industrial health and other activities. The Association has demonstrated leadership in campaigns for accident control in the home, on the highway and in industry. From the outset the organization urged the use of reason and understanding rather than emotional blindness in combating fanatic antimedical groups whose policies, if followed, would have forbidden the discovery of antitoxin, insulin and a number of other valuable agents whose therapeutic properties were humanely demonstrated on laboratory animals. It might be noted here that at no time has the American Medical Association ever made an appeal for funds from any agency outside its membership.

DOCTORS AT WAR

When a national peril has arisen the doctors of the nation have been among the first to don the uniform. In World War I approximately 38,000 physicians were in uniform. The American Medical Association turned its interest in the support of the national program toward successful prosecution of the war. Through educational channels and by other important practical measures it contributed to an increase in the efficiency of medical service. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was a most important medium in the distribution of information on military affairs, and in stimulating physicians to maintain medical service for the armed forces at a high level of effectiveness. THE JOURNAL carried articles on practically all phases of military medical service. Discussions concerning the base hospitals and the formation of hospital units appeared. In 1917 THE JOURNAL carried important data in regard to training camps. After World War I Gen. Merritt W. Ireland wrote to the President of the Association concerning the possibility of studying the experiences of the members of the medical profession during the war. Unsolved problems at that time included the consideration of representation of the medical department on the General Staff, control by the medical department of its own personnel, supplies and building program and, finally, appropriate recommendation concerning the qualifications of officers.

During World War II over 60,000 doctors at one time or another were in uniform. It has been stated that 90 per cent of the medical work was carried on by the reserves of the nation. The American Medical Association promptly mobilized for action when the war clouds began to loom. The Association at all times has a classified directory of its membership. The superb editorial and publishing facilities of the Association created a magazine entitled *War Medicine,* which carried important articles bearing on significant developments in this field.

In view of the importance of having a highly effective medical program available in the face of another national catastrophe, the House of Delegates directed that a study be made of the experiences of doctors during the last war. From the investigations which the committee appointed by the Board of Trustees has conducted, certain definite conclusions have been drawn. In the event of another war, and it is almost too much to hope that the world has seen its last conflict, it will be of the utmost importance to have an overall coordinated program built on the predicted medical needs of all portions of the population. In view of the unsettled state of international relationships the need for this program is imminent. Such a plan should be worked out with the consideration of all aspects of medical service, including the need for premedical selection and deferment, the assignment of doctors in appropriate categories, flexibility of mobilization, rotation of personnel and due attention to research. Such a program is not the sole concern of military authorities. It vitally affects every person in the nation, and certainly the American Medical Association with its membership of more than 130,000 cannot escape its responsibility in facing this challenge to national security. The nation trains just so many physicians per year, and the limited supply makes it of paramount importance that their talents be effectively utilized.

THE SUPPLY OF DOCTORS

Considerable comment has been offered in recent years on the number of doctors which the country now needs and will require in the future. Before the war there were more doctors per population in the United States than anywhere else in the world. After the outbreak of war classes in the medical schools were enlarged, the programs were accelerated and students were graduated in three years. With this stepped-up program some medical schools graduated one, and others graduated two extra classes, producing over 10,000 extra doctors in the last six years. Recently three new medical schools have been organized, and more are under consideration, particularly in the South. Due caution should be urged in plans for the establishment of more schools, since there is no essential relationship between the number of medical schools and the distribution of physicians. Costs of medical education are rising enormously, while at the same time the financial support, particularly from private sources, has diminished with equal rapidity.

Statistics indicate that there are approximately 2,000 more physicians being graduated per year now than the annual number of deaths among members of the profession. It must be admitted that shortages of physicians exist in certain areas of the nation. The statement that there are a great many counties in the various states without any physician at all is not especially significant, because many such areas are entirely too sparsely populated to require even one doctor in residence. Further, adequate medical facilities in adjacent counties are usually available. Greatly improved traffic lanes and excellent transportation facilities have minimized the problem of obtaining medical service on demand in hospitals or health centers. The avidity with which large numbers of persons move from place to place for medical attention, even passing excellent hospitals to obtain service at a distant point, suggests that there may be some additional satisfaction in the travel angle.

Approximately 40 per cent of practicing physicians were in military service. With a reduction of doctors on the home front the nation's health was better than ever. From this aspect one might conclude that the fewer doctors, the better the health of the people. As rapidly as it can be safely accomplished, the medical branches of the armed forces have been releasing physicians to inactive status. Instead of promptly returning to practice and thereby alleviating the need for doctors on the home front, a large number of discharged officers are engaged in postgraduate study. Some authorities estimate that up to 20,000 physicians who will ultimately return to civilian practice are still in graduate training.

In addition to those who have been discharged, the Army and Navy have inducted a large number of recent graduates who ordinarily would have entered private practice after internship or residency. Within a year or two this practice will be largely discontinued so that doctors recently graduating from schools and hospitals will be entering civilian practice in addition to the large number of older men who will in two or three years have finished their graduate training. With this sudden release of physicians into civilian practice there may in reality be more physicians than the country requires. Is this in the public interest? On the surface it would appear so. However, authorities believe it would react in just the opposite manner. When doctors do not have sufficient practice to keep busy and thereby earn an income to meet their needs, professional deterioration will occur and the incentive for advanced study is gone. With the loss of professional proficiency medical service deteriorates.

Finally it was recently stated before a congressional committee that more physicians should be trained because the armed forces are unable to recruit a sufficient number of doctors for the regular medical corps. Training more physicians will not create professional incentive for a career with the armed forces. The experience of a large number of civilian doctors during the recent war gave them an opportunity to compare practice under governmental control with private practice. With the creation of adequate professional opportunities for practice, study and research the medical service of the armed forces would be in a position to attract graduates interested in military medicine as a career. This problem is an important one in the interests of national security.

MEDICAL PREPAREDNESS

In the event of another catastrophe the use of atomic energy, biologic products, chemical agents and psychologic propaganda will, in all probability, represent the main types of military aggression. The medical needs of the nation must be determined in the light of this new knowledge. The use of these new and widely destructive agents must be kept in mind in any adequate program for the future security of the nation.

Organized medicine should play a prominent role in the formulation of a medical program that will require the participation of every physician in the nation. A National Emergency Medical Service Administration made up of representatives of organized medicine and related groups should make an exhaustive study of national needs. Appropriate recommendations need to be drawn up and presented to the President of the United States and the Secretaries of War and of the Navy. Past experience demonstrates the need for a peacetime program that will minimize the isolationism between the military medical services and civilian medical practice. Military medicine has many attractive features. Whatever shortcomings exist may readily be corrected by an impartial study of basic requirements.

SPECIALIZATION AND CERTIFICATION

In recent years specialization has advanced to a point where the majority of younger members of the profession are looking forward to some form of specialized practice. A survey indicated that a few years ago 67 per cent of the men anticipated limiting their practice to a particular specialty. Discussions on the role of the family physician and the future of the practice of general medicine have engaged the serious attention of the House [illegible] recent meetings. The Council on [illegible] has been advised to consider the possibility of recommending that general practice be developed as a specialty.

At a recent meeting of the Joint Committee for Coordination of Medical Activities a significant report was offered. In recognition of the importance of general practice, this committee pointed out that a Section on General Practice of Medicine has been created as a part of the Scientific Assembly. This is a definite contribution as far as it goes. It would be rather difficult to crystalize the boundaries and the limitations of general practice. Ordinarily the general practitioner is capable of handling the majority of the ailments of his clientele. When he needs help he calls for the specialist. The modern family doctor has adequate facilities at his command in the form of current periodicals and authoritative works by distinguished teachers. Postgraduate courses are being conducted throughout the length and breadth of the nation by county and state medical societies for the instruction of all physicians regardless of affiliation. These extension courses, some of which have been carried on in collaboration with various organizations, have proved eminently successful.

With the rapid increase in medical knowledge and the continuing improvement in medical training, graduates from the seventy-seven approved schools of the nation, regardless of their ultimate special field of practice, will require hospital facilities for the study and treatment of a certain number of their clientele. It is probable that the medical needs of the nation could be satisfactorily met if approximately two thirds of graduates would plan for general practice and one third prepare themselves for special fields. There are about 21,000 specialists certified by specialty boards and around 131,000 other practicing physicians at present.

The certifying boards were created to insure that the highest standards of performance would be furnished the public. For the purpose of measuring the qualifications of candidates for special practice, various written and oral examinations have been given. At no time has any suggestion been made by the specialty boards to any medical institution, school or hospital that certification should be a prerequisite for appointment to the faculty or staff.

ECONOMIC RESEARCH IN MEDICINE

With the advance of medical science and the elaboration of complex procedures for diagnosis and treatment, the costs of medical services have become increasingly important. Expensive hospital procedures and long continued illness are costly items which, without previous planning, have frequently proved burdensome. The American Medical Association has long been cognizant of this problem. Since 1930 the Bureau of Medical Economic Research has been investigating various aspects and encouraging studies in particular areas for the purpose of arriving at a practical and satisfactory solution. Although the majority of common ailments do not create a serious financial burden, prolonged illness and major surgical operations frequently do. The prepayment medical care plans which are being promoted by the American Medical Association and under which approximately six million citizens are now covered are designed to give the American people a chance to choose between "budget and bludgeon."

At present the Bureau of Economic Research of the Association is expanding its studies in this field under a professional economist. Under various plans voluntary health insurance has proved valuable to some forty million of the nation's population, as estimated from enrolment statistics. The American Medical Association has approved the principle of voluntary health insurance for hospitalization and medical care. The criterion on which approval is based is the requirement that a high quality of medical service be made available without interfering with the physician-patient relationship.

The American Medical Association will promptly support any suggested alteration in furnishing medical care to the nation which will in reality guarantee a higher quality of service.

OPPOSING FORMS OF GOVERNMENTS

Two philosophies of government are striving for supremacy in world affairs today. One believes in the dignity and the emancipation of the individual. It endeavors to guarantee freedom and opportunity for human betterment, imposing only those conditions which are necessary for the protection of society. In this form of government the state serves the people and is responsible to them. With adequate safeguards and checks the nation under this philosophy has flowered and grown strong.

The other form of government, in which the state is supreme, restricts individual liberty and continually limits individual rights and privileges. The vast majority of physicians in this nation is definitely committed to the democratic principle and combats vigorously any attempts to regiment the members of the profession and to make them subservient to a bureaucracy. If the trend of national affairs should move in the direction of socialism, then the professions, industry and labor must realize that their regimentation will not be long delayed. Compulsory taxation cannot be termed insurance, nor can health be gained by governmental decree. American medicine is dedicated to the high interest of social progress and will cooperate for the creation of a program of expanding medical service to all portions of the population. It will determinedly resist any visionary schemes that would embarrass the medical profession in its endeavor to furnish a satisfactory service to those in need. Comparative statistics from other nations have not demonstrated medical service superior to that of this nation. Nowhere has sickness been reduced; wherever the government has intervened between physicians and patients complaints have greatly increased in number.

A recent estimate indicates that the creation of a political medical program for this country would involve sums so tremendous as to be staggering in their totality. American medicine is keenly alert to the dangers lurking in visionary promises for governmental participation of a paternalistic nature that would reduce the quality of service and stifle professional initiative.

COMMUNITY HEALTH NEEDS

At present the American Medical Association is conducting a number of important investigations on community health needs, the distribution of doctors and the rural practice of medicine. It is particularly interested in hospital facilities and the maintenance of standards of hospital service.

The hospital is an important instrument for the public welfare. It has potentialities for education of the public as well as the members of the medical and nursing staffs. More and more the practice of medicine is stressing details of hygiene, prevention and prophylaxis of disease and the importance of early diagnosis. From an educational point of view the hospital should be a teaching center for the maintenance of health, the early recognition of disease and, finally, treatment. Members of hospital staffs in effect are engaged in the group practice of medicine. Some staffs are highly organized and definitely so regarded, while others carry on the spirit of group practice but are not so incorporated.

The central feature of the modern hospital should be the diagnostic clinic with a staff of general practitioners plus specialists as determined by community needs. The better the facilities for the study and treatment of disease in its incipient stages, that is, when patients are ambulatory, the less need will there be for confining patients to hospital beds for mere routine study. This field of rich opportunity needs much more development than has taken place to date. Augmentation of hospital staffs will furnish increased opportunity for general practitioners to participate in conferences and follow their own patients through the channels of investigation and treatment. Finally, members of the hospital staffs should be sufficiently interested in furthering the study of disease to carry on investigations from time to time and to make reports on carefully controlled observations. In this way the influence of medicine will continue to expand in each community and the level of service there will continually grow in proficiency.

PUBLIC RELATIONS

The interpretation of medical activities bearing on the health of the nation in terms of public understanding is a prominent responsibility of the members of the medical profession. Support and confidence of the public is essential to satisfactory medical care. To keep the channels open for informing the American public of significant events in the world of medicine the American Medical Association has developed a number of valuable activities. News releases, the use of the radio, *Hygeia* and units of the Woman's Auxiliary have functioned admirably. The relationship between the profession and the fourth estate, the ladies and gentlemen of the press, has always been most amicable. Due credit here should be given to the high quality of accuracy with which medical news has been interpreted in the lay press. Science has a constant ally so long as truth can be revealed uninfluenced by political pressure.

Public relations at the individual, community or national level is largely a matter of friendly understanding. When a large amount of important information bearing on the public welfare becomes available, its widespread dissemination is the proper function of organized medicine. With this in mind the Association is taking energetic measures to keep the public informed of its problems and accomplishments.

Members of the profession have an obligation to inform communities in which they reside of the ideals toward which medicine is striving. Too few doctors have schooled themselves in the art of expression before lay groups. As members of a learned profession dedicated to the welfare of their fellow men, physicians are unusually experienced in matters of social importance. It would appear, therefore, that an active part in community civic affairs would extend the influence of the physician and aid in offsetting the influence of visionary planners who are out of touch with reality.

MEDICAL ALLIES

This is an appropriate occasion for the doctors of the nation to express their gratitude to their loyal colleagues who have done so much in advancing the common cause, the "Nightingales" of America, the nurses without whom the present high quality of medical service would have been impossible of attainment. Organized medicine is in close touch with the perplexing problems facing the nurses today and will furnish every assistance possible in reaching solutions to bring greater satisfaction and security to those engaged in one of the noblest of the arts.

Medicine requires libraries for education, precision instruments for performance and accurately assayed drugs for treatment. The story need be told of those groups who create the volumes, instruments, and drugs for the profession. In these fields a precision of technic is required which permits no inaccuracy. It is of the greatest importance that those articles which are the doctor's stock in trade should be of the best quality and usefulness.

The allies of the medical profession have the same goal as the physicians, the same triumphs and defeats. In a sense they complement one another; the success of one reflects credit on all.

Some of the finest research in the medical world at the present time is being carried on in laboratories of large pharmaceutical organizations. They have called into counsel leading authorities from the far ends of the earth. Any performance less than the best is not acceptable.

It should be emphasized that laboratories for medical research are not the sole concern of medical faculties or the foundations. High credit is due those organizations which have joined forces in exploring new fields in a search for more effective weapons in the control of disease.

In the enchanting field of research a number of allied groups are engaged, colleagues in the same cause, using the same blueprints and libraries for reference. Plans are worked out together, and when success crowns any project one group prepares the product and the physicians administer it.

The kinship of various groups allied in a common cause offers a guaranty of continued progress in the advancement of medical knowledge.

SOCIAL MEDICINE

Medical statesmen have a role to perform in helping to shape the destiny of national affairs. Doctors are interested not only in the physical health but, of even greater importance, in the peace of mind of their clientele. These turbulent times precipitate sharp clashes between individuals and their environment that are reflected in physical or mental ailments which send folks, heavyhearted, to their family physicians.

The medical practitioner today is studying not only the individual but his relationship and reaction to other members of his family and his community. Unstable society is likely to engender an increased number of neurotic reactions on the part of citizens. Family doctors in the role of shock troops of modern medicine study their patients in the light of these social problems. There is nothing essentially new in the story of social medicine and its pathology. Whereas individual pathology considers the disorders of the patient, social pathology reflects the disorders of his surroundings. While the terms are new the problems are old. The increasing number of patients with hypertension, peptic ulcer, thyroid disease, rheumatic disorders and the neuroses reflects the inability on the part of these patients to adjust to the tempo of modern society. Medicine's field of vision has expanded in accordance with the changing pattern of the diseases of modern civilization, and the physician is energetically inquiring into improving the methods of their control.

CHARTING NEW SEAS

Medical research has sharpened its weapons for probing the secrets of those common disorders which threaten human existence. The real zest of life is at the growing edge where the frontiers are expanding. Research workers probe into the terrain of the unknown and, in the last quarter century, have discovered new methods for the control of the anemias, diabetes, infectious and contagious diseases, nutritional deficiencies and for the correction of abnormalities which previously threatened life. With the onward march of medical science the diseases which exacted such a large toll in infancy and the early years have been brought under control.

Across the centuries many improvements have come through social progress. While no comprehensive measure or index is available, we can regard each specific accomplishment in the broad area of social progress as being reflected in the length of human life. Twenty centuries ago the life expectancy of Roman citizens of the upper class was approximately twenty-five years. In 1847, the year when the American Medical Association was founded, the average future lifetime at birth was approximately forty years. In 1947 it is estimated to be almost sixty-seven years. Hence on the occasion of this Centennial celebrating one hundred years of organized medicine, there can also be celebrated a century of phenomenal progress in man's fundamental attempt to avoid death. A gain of from approximately forty years to almost sixty-seven years as of June 1947 is indeed one of the greatest accomplishments in the history of mankind. We salute the American people on this great achievement in survival. Truly, we are today celebrating the century of the greatest social progress in the history of the human race.

The doctor of medicine has been the agency through which most of these fundamental improvements in man's environment and in the control of disease have actually reached the people. Organized medicine can look back on this century with the assurance of a great contribution to the efforts of the American public to continue living longer.

Great as has been the advance of medicine in the past twenty-five years, even more spectacular is the promise for medicine during the next quarter century. The American public can rest assured that the members of the medical profession in this land will carry on a never ceasing battle to bring the destructive agents under control and free the population from the hazards that interfere with the daily lives of so many. The scientific method indeed is paying rich dividends in probing the realm of the unknown; yet to be clarified are the major problems of today which influence and govern the conduct of each individual. In the words of Walter B. Cannon, "It is the inhumanity of human beings that spoils the achievements of science." If on the one hand the atomic age has brought the atomic bomb, on the other it offers highly effective weapons for the enhancement of human existence.

Civilization is at the crossroads and must decide in what direction to go. Cannon asks what can be done to improve human behavior and describes it as the supreme challenge, the most important frontier yet to be explored. The scientific method, the search for truth—therein lies the hope for more stable relationships. While the scientific method has had spectacular triumphs in revealing the mysteries of the physical world, its greater opportunity lies in the direction of probing those forces which control the activities of men.

There are potent biologic factors which shape human destinies, only a few of which have recently been evaluated. Progress has been made, however, in the realm of the endocrine glands. A cretinous youngster may be transformed into a normal child. Violent reactions of an emotional nature can be evoked or abolished at will by experimental means. Cannon has opened the door and indicated what lies within. He states that physicians are now beginning to learn more about the fundamental traits common to man and his humbler relatives. Possibilities now exist of becoming acquainted with powerful factors which may deeply affect human dispositions and reactions to external conditions. Medical science now is beginning to utilize the experimental method for understanding man's reactions and ways of influencing them.

Man is not a reasonable creature; he is ruled by his impulses and emotions. These determine his actions. In the interest of self preservation science today needs to study the basic fundamental traits that influence the dispositions and actions of men. Herein is the great challenge, the new frontier, the hope of mankind.

In an address before this Association in 1910 Dr. W. H. Welch, then President, described organized effort as a distinguishing mark of modern civilization, as essential for the advancement of science as for the promotion of commerce.

New knowledge has given the family physician a greater control of the disorders which threaten the health of his patients. Organized medicine is taking the lead in improving the conditions of the worker in home, school, field and factory. On the occasion of the Centennial Celebration, the American Medical Association experiences a just pride in the accomplishments of American medicine and in the contributions the Association has made in the spheres of medical education and public enlightenment. It enters its second century with abundant vitality and renewed vigor, steadfast in purpose and confident in its ability to attain even greater objectives for the benefit of mankind

TREATMENT OF DUODENAL ULCERS

Partial Gastrectomy versus Palliative Resection

RICHARD LEWISOHN, M.D.
New York

In 1927 I presented, before the American Medical Association, a paper on partial gastrectomy versus gastroenterostomy in the surgical treatment of duodenal ulcers.[1] At that time the group of physicians performing gastroenterologic surgery at the Mount Sinai Hospital then headed by Dr. A. A. Berg was trying to introduce gastric resection with removal of the duodenal ulcer as an operation of choice.

The importance of this more radical operation for the avoidance of postoperative peptic ulcer was first emphasized by Haberer[2] in 1920. He pointed out that in order to achieve satisfactory results three criteria had to be met: (1) removal of the duodenal ulcer, (2) removal of the pylorus and (3) resection of at least 60 per cent of the stomach. The omission of the first two steps of this procedure cannot be compensated by increasing the extent of the resection toward the cardia.

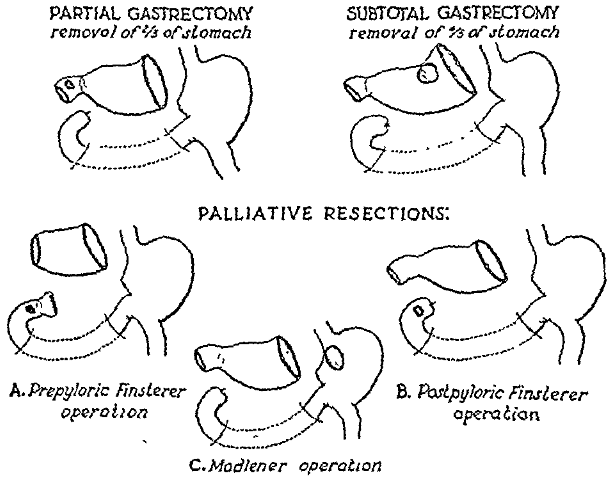
At the outset the views of this group encountered widespread opposition. As time passed, however, a gradually increasing reversal of opinion was noted among many surgical colleagues. Today, advocacy of gastroenterostomy as the method of choice in the treatment of duodenal ulcer would probably be criticized as severely as was the recommendation of partial gastrectomy twenty years ago.

Though gastroenterostomy has lost most of its supporters as a method of choice, it is still used extensively in this country as a method of expediency. For instance, in 1944 surgeons at the Mayo Clinic[3] performed gastroenterostomies in 37 per cent of the cases of duodenal ulcers.

The terms subtotal gastrectomy and partial gastrectomy as applied to the operation for duodenal ulcer are apparently defined in a variety of ways by different surgeons. These variations have become so divergent that it seems wise to reiterate the proper definition of these terms. The expression subtotal gastrectomy was originally and correctly employed to describe the operation necessitated by the resection of extremely large gastric ulcers. It should be emphasized that this includes transection distal to the pylorus and the removal of four fifths of the stomach proximal to it.

In the early days of radical surgical intervention for duodenal ulcer (I use the word radical in contradistinction to local excision, pyloroplasty, gastroenterostomy, Eiselsberg or Finsterer operations) the term partial gastrectomy was used. Partial gastrectomy or gastric resection meant one thing then and should mean only one thing now, namely, removal not alone of two thirds of the stomach but of the pylorus and the duodenal ulcer as well. Operations which deviate from this technic should not be called partial gastrectomy for duodenal ulcer. For instance, if either the duodenal ulcer or the pylorus, in part or in toto, is left in situ, the procedure should be classified as palliative resection, a classification which has been employed by different authors for many years. If a surgeon removes part of the stomach and leaves the duodenal ulcer in its place, he is not warranted in calling the operation partial or, worse yet, subtotal gastrectomy. Unless a proper nomenclature is strictly adhered to, the records will be hopelessly confused. Unsatisfactory results will be attributed to partial gastrectomy in cases in which this operation had really never been performed (fig. 1).

The dangerous spread of a lax nomenclature even in some of the leading centers of surgical teaching is evident from a recent statement by McKittrick:[4] "At the Massachusetts General Hospital subtotal resection is the accepted operation for intractable duodenal ulcer. By subtotal resection we mean a removal of the distal two thirds of the stomach to or beyond the pyloric ring or the removal of all the distal two thirds except a small segment of the antrum from which the mucosa has been excised." McKittrick gives a good description of the so-called prepyloric and postpyloric resections, which were described by Finsterer[5] in 1918, a few years before Haberer showed the importance of the removal of the duodenal ulcer and the pylorus. The Finsterer operations may in rare instances be employed as makeshift operations in nonresectable ulcers. They should never be classified as subtotal gastrectomies. Finsterer considered his operations as methods of expediency for nonresectable duodenal ulcers in close proximity to the papilla of Vater, not as methods of choice. In ulcers situated in the first part of the duodenum (by far the most frequent location of the ulcers) he advised a typical gastric resection, both for anterior and posterior duodenal ulcers.



PARTIAL GASTRECTOMY
removal of 2/3 of stomach
SUBTOTAL GASTRECTOMY
removal of 4/5 of stomach
PALLIATIVE RESECTIONS:
A. Prepyloric Finsterer operation

easily resectable ulcer in situ is favored by the present group in charge of gastric surgery. Colp[7] recently reported about the material on his ward service (1937-1943) at Mount Sinai Hospital. He stated that among 173 resected cases only 102 specimens contained the ulcer. In addition 48 (21 per cent) gastroenterostomies were performed. In other words, his group performed a typical gastric resection with removal of the duodenal ulcer in less than half of the cases. On his service every gastric resection, whether the duodenal ulcer is removed or left in situ, is classified as subtotal gastrectomy. Other surgeons in this hospital have reserved the term of partial or subtotal gastrectomy for those cases in which the duodenal ulcer was removed. With this wide divergence in classification any accurate statistical evaluation of the material seems impossible. Naturally the same impasse will be reached in other institutions, unless a uniform nomenclature is adopted by every surgeon.

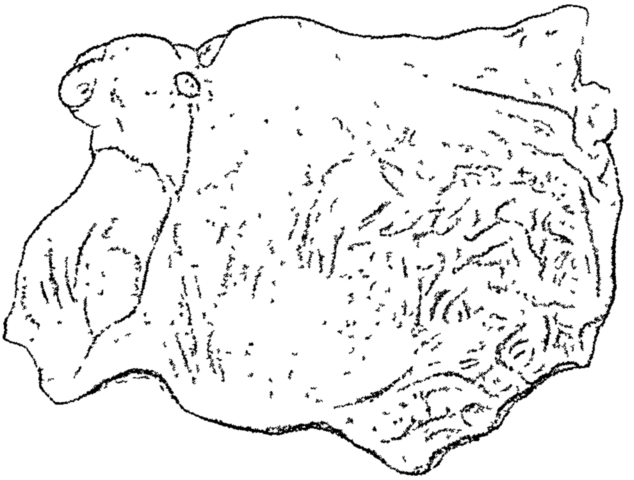

Fig. 2.—Duodenal ulcer in close proximity to the pylorus.

It is of the greatest importance to adhere closely to the correct technic in the treatment of duodenal ulcers. Removal of part of the stomach without removal of the ulcer will put the clock of progress back. It may present the mirage of an easy solution of a sometimes difficult technical problem, but it will fail to achieve good permanent results. For this reason the so-called postpyloric Finsterer operation was abandoned many years ago, except as a method of expediency in a relatively small group of cases. The recent attempt to revive this method will lead again to failure.

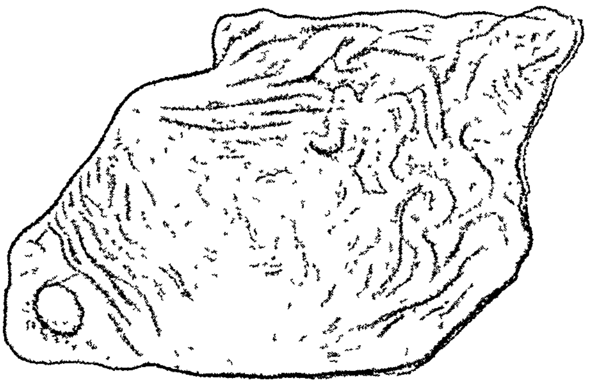

Fig 3.—Duodenal ulcer on the posterior wall penetrating into the head of the pancreas. Pronounced inflammatory reaction surrounding the ulcer.

It seems peculiar that the importance which the complete removal of the pylorus plays in insuring satisfactory end results after partial gastrectomy for duodenal ulcers does not seem to be appreciated by many American surgeons. It is evident that some surgeons in this country try to steer a middle road between partial gastrectomy and gastroenterostomy. Undoubtedly they overestimate the inherent risks of including the duodenal ulcer in the gastric resection. The fact that an ulcer is situated on the posterior wall of the duodenum or that it is adherent to neighboring organs like gallbladder, colon or pancreas is not sufficient reason to declare an ulcer not resectable. However, as in subtotal gastrectomies for large gastric ulcer on the posterior wall with dense adhesions to the pancreas, it is occasionally advisable to cut around the duodenal ulcer and leave its base on the pancreas.

Two technical points are of great importance in dealing with duodenal ulcer: (1) The line of dissection should be below, not above, the ulcer, and (2) a sufficient portion of normal duodenum should be freed on its posterior wall from the surrounding tissue, especially the pancreas, to allow a safe closure of the duodenum.

The frequent impossibility of leaving the duodenal ulcer in situ and simultaneously establishing a safe closure of the duodenum is well demonstrated in a number of drawings which I published in a paper entitled "Persistence of Duodenal Ulcers After Suture of an Acute Perforation."[8] These drawings show that it would have been impossible to exclude the ulcer from the resection without leaving the pylorus or part of the pylorus behind. In the first specimen the ulcer was located right at the pylorus (fig. 2). In the second case the punched-out ulcer was surrounded by an area of intensive inflammatory tissue, which fixed the ulcer to the pancreas (fig. 3). In order to free the ulcer properly a part of the pancreas had to be resected. The patient made an uneventful recovery. If the ulcer had been left behind, the surgeon would undoubtedly have left part of the pylorus and possibly part of the antrum in situ. Most duodenal ulcers are located on the posterior wall either as single ulcers or as so-called kissing ulcers just beyond the pylorus. The operation of partial gastrectomy was not devised to include only easily resectable ulcers on the anteroir wall of the duodenum.

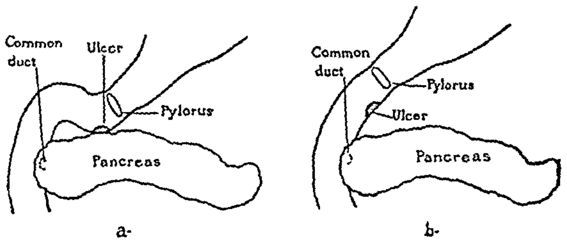

Fig 4.—Duodenal ulcer in its relation to the pancreas and common duct (*a*) before and (*b*) after the freeing of adhesions (diagrammatic)

An ulcer on the posterior wall may, at the outset, give the impression that its removal would not leave sufficient space below the ulcer for a safe closure of the duodenum. However, figure 4 shows that by properly freeing the ulcer from the pancreas the removal of a duodenal ulcer which seemed to offer considerable difficulty was transformed into a simple technical procedure.

[7] Colp, R.; Klingenstein, P.; Mage, S., and Druckerman, L. J.: Subtotal Gastrectomy for Duodenal Ulcer, Ann. Surg. **120:** 170, 1944.

[8] Lewisohn, R.: Persistence of Duodenal Ulcers After Suture of an Acute Perforation, Surg., Gynec. & Obst. **64:** 172, 1937.

The statement is frequently made that cases of duodenal ulcer with pyloric obstruction can be satisfactorily managed by gastroenterostomy. This is based on the mistaken idea that pyloric stenosis is usually due to scar obstruction and that the active ulcer is healed. Actually many of these stenoses are due to the inflammation and edema present about one or more active duodenal ulcers (fig. 5). Unless such patients are subjected to adequate resection, the danger of subsequent jejunal ulcer is considerable

Success or disaster in gastric resection depends mainly on a safe closure of the duodenal stump. Even if it is possible to remove the pyloric ring in its entirety, the structures between the pylorus and the upper margin of the ulcer are usually so changed that a safe suture of the duodenum is impossible. In order to reach normal duodenal tissue the duodenal ulcer must be included in the resection The duodenum should be freed sufficiently far on the posterior wall to allow an adequate two layer suture. The most important layer of suture is the first layer. Unless this suture is inserted with the greatest care a leak may occur. A second row of sutures reenforces the first layer. In some instances a third row of sutures may fix the duodenal stump to the capsule of the pancreas, thus burying the entire stump. As a rule drainage is not only unnecessary but contraindicated.

Drainage of the abdomen through a stab wound in the right flank as a method of choice is advocated by many surgeons who leave the ulcer in situ. It is the best proof that they are not convinced of the safety of the duodenal closure. Surgeons who complete the duodenal closure distal to the ulcer and thus are able to establish a safe suture line, find the use of drainage unnecessary in most cases. When a leak occurs the postoperative course is inevitably prolonged. Those who advocate leaving the ulcer in situ should publish not only their mortality but their morbidity figures.

The only reason for the unnecessary ultraconservatism in dealing properly with duodenal ulcers is an unduly exaggerated fear of postoperative pancreatitis. It is surprising that in spite of the progress which has been made in the surgery of the pancreas in recent years, some surgeons seem afraid to remove duodenal ulcers which disclose definite adhesions to the pancreas which may require sharp dissection.

No experienced gastric surgeon will deny that one occasionally encounters nonresectable duodenal ulcers, mainly those which involve the common duct so intimately that radical removal with dissection from the duct cannot be safely performed. Furthermore, the general condition of the patient may be so precarious that any major operation is contraindicated. For these two groups of cases, which are indeed rare (certainly not more than about 5 per cent of the duodenal ulcer material), a simple gastroenterostomy is the best method.

The conviction still widely held, that resection for duodenal ulcer is inevitably accompanied by an inherent high mortality, is certainly not substantiated by the amazingly low mortality figures reported by some clinics. For instance, Lahey[9] and his associates have performed 530 consecutive gastric resections for duodenal, gastric and jejunal ulcers with a mortality of 1.5 per cent. Incidentally, it should be pointed out that gastroenterostomies or palliative resections for duodenal ulcer are seldom performed at the Lahey Clinic. Naturally, it is impossible to achieve such excellent results, unless a perfect organization representing surgery, medicine, gastroenterology, laboratory and x-ray departments cooperates. Furthermore, the surgeon must have acquired a perfect technic for the duodenal resection. This type of surgical intervention cannot be performed by the general surgeon with a small gastric material. His mortality figures will be unduly high.

While some surgeons may attempt to defend the practice of leaving the ordinary chronic duodenal ulcer in situ, even the most convinced proponent of this method must admit that the situation is quite different in an ulcer complicated by uncontrollable hemorrhage. For reasons which will be demonstrated later, it is particularly in this type of case that the operative experience acquired by the surgeon who habitually resects distal to the ulcer will prove its usefulness.

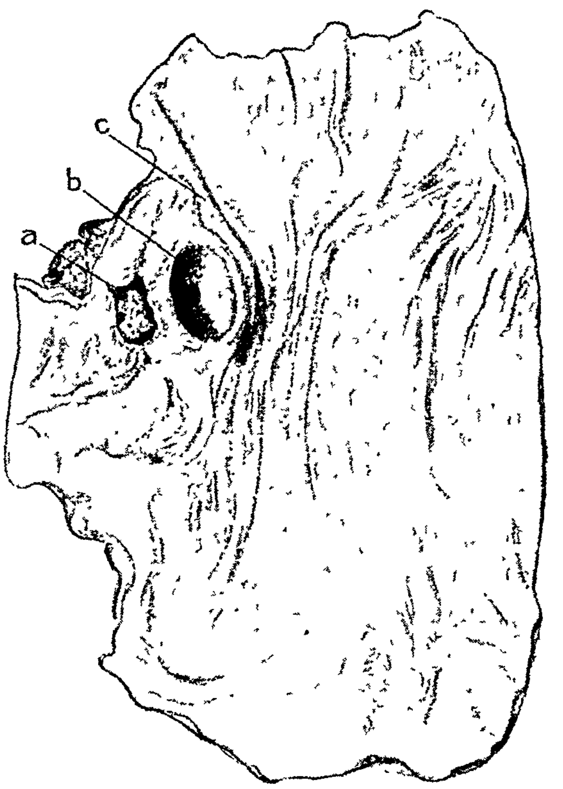

Fig. 5—Specimen showing a duodenal ulcer (*a*) on the posterior wall and a diverticulum (*b*) just beyond the pylorus (*c*).

At present considerable confusion exists as to the natural course and therapeutic indications of bleeding duodenal ulcers. This is largely due to a failure to differentiate and classify properly the various types of bleeding that are encountered. The situation will be considerably clarified if hemorrhage due to duodenal ulcer is divided into three groups: (1) mild hemorrhage of an ulcer which stops spontaneously after only slight loss of blood and with a *minimum* of constitutional symptoms; (2) severe bleeding which stops after a few blood transfusions, and (3) uncontrollable hemorrhage which remains unaffected after a number of blood transfusions. Obviously if the first group, which constitutes a large proportion of all cases, is grouped with the other two, an erroneous concept as to the potential dangers of the severer types of bleeding may be acquired. Group 3 may be small in number as compared with group 1 or 2. However, group 3 represents one of the most serious problems in the treatment of ulcers. In 1943, for instance, 52 patients were admitted with bleeding duodenal ulcers to the medical wards of Mount Sinai Hospital. In 21 cases the bleeding was so mild that the patients recovered without a transfusion. Thirty-one patients received one or more transfusions. These 31 cases represent hemorrhage of groups 2 and 3. Four patients died. It should be noted that other authors have reported considerably higher mortality figures.

---

[9] Marshall, S F Recurrent Ulcer Resulting from Inadequate Gastric Resection, Lahey Clin Bull. 4: 182, 1945.

The mortality for severely bleeding ulcers would be even higher if those cases in which bleeding, though profuse, stops after a few transfusions were separated from those in which it continues after a number of transfusions. It is in this latter group that surgical procedures must supplant medical treatment, if the patient is to be saved. It is in this latter group that the mortality will be high unless, as Finsterer[10] pointed out, these patients are operated on before they are so hopelessly exsanguinated that the tissues have lost their recuperative power. It is in this latter group that supreme technical skill is needed in order to save the patient's life by a rapid gastric resection. The bleeding occurs in most cases in an ulcer situated on the posterior wall with an open vessel in the center of the ulcer. Transfixion or cauterization of the ulcer, as Rienhoff[6] has advised, often is technically impossible and may not prevent continuation of the hemorrhage with subsequent fatal issue. Attempts to tie off the afferent vessel will usually prove futile, as it is in most instances a branch of the pancreaticoduodenal artery which cannot be reached without prior removal of the duodenal ulcer.

In certain circles the opinion is apparently held that operation during the active stage of hemorrhage is practically always unwarranted. It is my opinion that a more aggressive attitude in the surgical treatment of bleeding duodenal ulcers will result in a lower mortality. Without such surgical intervention a number of patients in whom hemorrhage has not ceased after a series of transfusions will go on to a fatal issue. Age is not a definite criterion, though most of the fatal cases occur in the higher age groups (above 45).

SUMMARY

1. The term "partial gastrectomy for duodenal ulcer" should be used only when the gastric resection includes the removal of the duodenal ulcer.

2. If the duodenal ulcer is left in situ the operation should be classified as palliative resection.

3. The term "subtotal gastrectomy" implies that a small pouch of stomach remains after the gastric resection. It should never be used in describing gastric resection for duodenal ulcer, which does not remove more than one half or two thirds of the stomach.

4. In order to guarantee a complete removal of the pylorus and a safe closure of the duodenum, the resection should be carried below the ulcer.

5. I strongly advise against the technic which leaves the ulcer in situ. Such a procedure is apt to be followed by an increase in immediate postoperative complications and an increased incidence of jejunal ulcers.

6. Abdominal drainage is unnecessary and inadvisable in most cases. It indicates that the surgeon is not satisfied with the safety of the duodenal suture.

7. In most bleeding duodenal ulcers the hemorrhage stops spontaneously or after a few transfusions.

8. However, in a small percentage of these cases, partial gastrectomy must be employed as the only possible procedure in an attempt to save the life of the patient.

1155 Park Avenue.

ABSTRACT OF DISCUSSION

DR. FRANK H. LAHEY, Boston: I agree with practically everything that Dr. Lewisohn has said. I should think that he would get a great deal of satisfaction in presenting this subject, particularly in view of the difficulties that he and several others in this country who were pioneers in advocating subtotal gastrectomy had in gaining the acceptance of subtotal gastrectomy. That was the period of debate in regard to the value of gastroenterostomy versus subtotal gastrectomy and the mortality of gastroenterostomy as compared with the mortality of subtotal gastrectomy. Surgeons are now on the threshold of another comparison, and that is a comparison of the results with the method of treating gastric and duodenal ulcer by vagotomy with those of subtotal gastrectomy. The comparison of the results of subtotal gastrectomy with those of vagotomy is at a very early stage. It will be interesting to observe whether these results are compared and reported with greater tolerance, justice and consideration than were the comparisons between gastroenterostomy and subtotal gastrectomy. During the period while subtotal gastrectomy was being put on probation its opponents became stirred up and not a little unfair. Not only was this attitude an injustice to the men who strongly urged subtotal gastrectomy at that time but I am sure that the results with gastroenterostomy were not reported as scientifically and as justly as they should have been. As a result of these experiences reports on results and comparisons between subtotal gastrectomy and vagotomy as a method of treating peptic ulcer will be made much more scientifically and much more justly than was the comparison between gastroenterostomy and subtotal gastrectomy. There are certain things about vagotomy that all will watch with interest. One is, as the result of the atony which occurs after vagotomy, how many of these vagotomized patients, particularly those with duodenal ulcer, which so frequently produces some degree of obstruction, will need later gastroenterostomy? Since vagotomy only temporarily lowers acidity, if gastroenterostomies have to be performed, how many gastrojejunal ulcers will later follow this procedure? When one realizes that extremely active duodenal ulcers cicatrize when healing and frequently produce some degree of obstruction, the combination of cicatrix plus atony can and probably will make it necessary to follow vagotomy later by an as yet unproved number of gastroenterostomies. Because of this uncertainty, my position and that of my associates has been that we will reserve vagotomy for those patients with complicated ulcers in whom we consider that an operation as yet unseasoned is justified in terms of risk, such as the patients who have had high subtotal gastrectomies and in whom recurrent jejunal ulcers have later developed. In these cases we would be quite willing to perform vagotomies, because in spite of the gastrojejunal ulcer they will, with a large stoma, drain even though atony occurs. As yet I do not want to perform many vagotomies for duodenal ulcers in relatively young persons when there is an other well proved operation, tested over the years, that gives reasonably good results; however, I do feel that vagotomy is a real contribution, and it is of value to have another method of approach. I hope it works because it is technically much easier on the surgeon than a subtotal gastrectomy for duodenal ulcer which has to be taken off the common duct. When one compares the mortality between gastric ulcer, duodenal ulcer and jejunal ulcer, all operated on by subtotal gastrectomy, as shown in our series (85 gastric ulcers—

[10] Finsterer, H.: Surgical Treatment of Acute Profuse Gastric Hemorrhage, Surg., Gynec. & Obst. 69: 291, 1939.

no mortality, 358 duodenal ulcers—mortality 2 8 per cent, and 87 jejunal ulcers—mortality 2 3 per cent), it may be seen that the mortality is highest in subtotal gastrectomies for duodenal ulcers This is due to the fact that so many of these ulcers are old, have become adherent to the common duct and have eroded into the head of the pancreas What has this to do with gastroenterologists? I strongly urge that the patient with a chronic duodenal ulcer that has recurred frequently be submitted to operative intervention earlier than has often been the case in the past, before the erosion of the pancreas, cicatrization and adherence to the common duct have taken place Many of these complications which produce the mortality with duodenal ulcer can then be technically avoided We at the Lahey Clinic have demonstrated, I think, as have all men who do much gastric surgery, that subtotal gastrectomies can now be performed with relatively low mortality We are seeking, all of us, to lower this mortality rate even more, and one method, particularly with the duodenal ulcers, by which this can be accomplished is their resection before they have become so cicatrized and have eroded so deeply into the pancreas

GASTRIC OPERATIONS

Troublesome Postoperative Symptoms with Special Reference to Carbohydrate Ingestion

ROBERT M ZOLLINGER, M D
Columbus, Ohio
and
STANLEY O HOERR, M D
Boston

There has been a tendency to consider gastric operations successful if a recurrent benign or malignant ulceration does not develop While it has been recognized that after such procedures patients may have difficulty in regaining their preoperative weight and some may require treatment for a secondary anemia, it is doubtful if physicians at large have accepted the fact that 5 to 25 per cent of these patients have complaints which are related to the ingestion of food[1] These symptoms may occur as a mild or severe attack which includes some or all of the following. sensations of warmth, sweating, dizziness, faintness, palpitation, nausea and abdominal pain Extreme instances of syncope or convulsions are cited in the literature, whereas mild attacks may simulate hunger pains or the hot flushes of the menopause Attacks may come on either immediately after eating or several hours later A study of a group of patients who had had various types of gastric operations suggests that these symptoms are commoner than is generally realized and are related to a diet rich in carbohydrates

The cause of this syndrome has been the subject of considerable speculation In 1933 Lapp and Dibold[2] corroborated by Beckermann[3] called attention to the occurrence of spontaneous hypoglycemia with typical symptoms several hours after meals They found that dextrose tolerance tests performed in patients who had had gastric operations showed abnormally steep curves, with the blood sugar rapidly rising to levels above normal and subsequently falling to below normal. Inasmuch as a similar curve could be produced by injecting solutions of dextrose directly into the jejunum, it was assumed that the alteration in the curve reflected an increase in the rate of absorption of the sugar rather than a change in sugar tolerance and that it was presumably due to more rapid delivery of the sugar into the jejunum. The treatment of patients subject to such attacks should obviously be aimed at supplying sugar in some form well before the onset of this alimentary hypoglycemia.

Glaessner pointed out in 1940[4] that alimentary hypoglycemia was not responsible for all the symptoms in these patients. He showed that a diametrically opposite condition, which he termed hyperglycemic shock, was present following the administration of dextrose or sucrose in certain patients after gastric resection. This was associated with "nausea, vomiting, lumbar pains, visual disturbances, convulsions and cardiac disturbances." It was his belief that the rapid absorption of dextrose or sucrose accounted for these symptoms and that the hypoglycemia was a delayed and secondary effect He advocated the use of small doses of insulin before meals by patients who exhibited these symptoms.

Other investigators have expressed the view that there is no close correlation in these patients between the rate of sugar absorption and the symptoms. They believed the attacks to be the result of sudden, mechanical *distention of the unprepared jejunum.*[5] This has been called the dumping syndrome Custer and associates[1a] described it as occurring suddenly, either during or immediately after a meal, and listed four cardinal symptoms: "(1) profound nausea and weakness, (2) a generalized and unpleasant sense of warmth throughout the body, (3) a cold diaphoresis of the face, particularly of the forehead, and (4) cardiac palpitation." They found the incidence of this syndrome to be 5 per cent and 12 5 per cent in two groups of patients who had had gastric resection for benign peptic ulcer. Since the majority of the patients had a resection of the Polya type, they were inclined to relate the syndrome to the large gastrojejunal stoma · They considered that prevention of this complication was logically directed at creating smaller stomas in the future (as in a Hoffmeister type of resection) to delay gastric emptying They sought to slow down the emptying of the stomach by having the patients lie down immediately after meals, by giving ephedrine before meals and by the oral administration of dilute hydrochloric acid Although these writers did not believe that the size and nature of the feeding were important factors, they stated that one fifth of these patients implicated sweets, carbohydrate-rich foods and milk as initiating the attacks

Evenson[6] conducted a careful study of dextrose tolerance curves and gastric motility in normal controls, in patients with medically-treated gastric or duodenal ulcers, in patients with gastroenterostomy and in patients with gastric resection He was able to reach the following conclusions: 1. Gastric motility and speed of emptying is increased in patients who

have had a gastric resection or a gastroenterostomy. 2. The dextrose tolerance curve is abnormal in the majority of patients with gastroenterostomy or gastric resection, showing a great and rapid primary rise and a subsequent rapid fall to low values. 3. The abnormal dextrose tolerance curves are the result of speedier absorption from the jejunum; this in turn is a consequence of rapid gastric emptying. In 1 case of unusual interest a gastroenterostomy of some years' standing was demounted, and normal gastroduodenal continuity was restored. With elimination of the gastroenterostomy, abnormal dextrose tolerance curves of the type referred to previously became normal, and the gastric emptying was found to be slowed.

TABLE 1.—*Sugar Absorption After Gastric Surgery*

Oral Dextrose Tolerance Tests

Blood Sugar Curve	No of Patients
Both hypoglycemia and hyperglycemia	10
Hyperglycemia only	7
Hypoglycemia only	4
Neither hyperglycemia nor hypoglycemia	4
	25

Hyperglycemia greater than 250 mg per hundred cubic centimeters
Hypoglycemia less than 65 mg per hundred cubic centimeters

The present study of bizarre symptoms after gastric operations is based on a group of 25 patients, a number of whom were selected because they had complaints related to eating. Of the 25 patients, 15 had submitted to various surgical procedures for duodenal ulcer, including gastroenterostomy, Billroth I resection, Polya resection and radical fundusectomy. Five patients had marginal ulcers in a previous gastroenterostomy, and 3 of these had subsequent resection. Two patients had resection for gastric ulcers. Three patients had resection for carcinoma, including 1 total gastrectomy. There were 21 men and 4 women in the group, and their ages varied from 26 to 65 years. The elapsed time following the operative procedure varied and was over twenty years in some cases.

These patients were given 100 Gm. of dextrose orally after they had fasted, followed by blood sugar determinations at frequent intervals for about three hours. Any complaints which developed during the period of observation were noted, and their character, severity and duration recorded. Most patients had two or more tests. In a few cases test meals of high carbohydrate, high protein or high fat content were used as well. For purposes of analyzing the group as a whole, a curve was regarded as showing hyperglycemia if the blood sugar level exceeded 250 mg. per hundred cubic centimeters in an hour or less, and as hypoglycemia if the blood sugar dropped below 65 mg. per hundred cubic centimeters after the first hour.

TABLE 2.—*Sugar Absorption After Gastric Surgery*

Symptoms During Dextrose Tolerance Test in Patients with Peptic Ulcer

Symptoms	No. of Patients	Curve *
Both early and delayed	5	5 had hyperglycemia and hypoglycemia
Early only	8	6 had hyperglycemia
Delayed only	1	1 had hypoglycemia
No symptoms	8	
	22	

Hyperglycemia greater than 250 mg per hundred cubic centimeters
Hypoglycemia less than 65 mg per hundred cubic centimeters

* Includes only portion of curve associated with symptoms

Ten of the patients had both hypoglycemia and hyperglycemia in one or more dextrose tolerance tests (table 1). Seven patients showed only hyperglycemia, while 4 showed only hypoglycemia. All but 4 patients in the entire group of 25 showed either hypoglycemia or hyperglycemia, or both, in one or more dextrose tolerance tests. This is in accord with the observations of others previously referred to, that abnormal curves are to be expected in this type of patient.

An analysis of the 22 patients with peptic ulcer (table 2) shows that 14 had some type of complaint, exclusive of a feeling of fulness or drowsiness, in the course of the dextrose tolerance test. Furthermore, in all but 2 of the 14 there were corresponding abnormalities in the blood sugar level. It should be emphasized, however, that the time of the complaint did not necessarily coincide with the extremes of the blood sugar level. Early symptoms frequently appeared before the greatest peak, and late symptoms in several cases lagged behind the first drop to hypoglycemic levels. Patients experiencing discomfort both early and late in the test invariably were asymptomatic in the interval.

TABLE 3.—*Sugar Absorption After Gastric Surgery*

Correlation of Clinical Symptoms with Dextrose Tolerance Test in Patients with Peptic Ulcer

No of Patients	*Complaint on Follow Up*	*Dextrose Tolerance Test*	
4	Symptoms within 30 minutes of eating	Early symptoms	4 –
		Hyperglycemia	3 *
6	Symptoms delayed an hour or more after eating	Delayed symptoms	3 †
		Hypoglycemia	5 †

Hyperglycemia greater than 250 mg. per hundred cubic centimeters
Hypoglycemia less than 65 mg per hundred cubic centimeters

* Does not include late phase of test
† Does not include early phase of test

Ten of the 22 patients with peptic ulcer gave a history of postoperative discomfort, which could reasonably be interpreted as of the type considered in this study (table 3). These symptoms are more frequently associated with breakfast than any other meal. The 10 patients can be divided into two groups: in one the symptoms appeared shortly after eating; in the other they came on after a latent period of one hour or longer. Table 3 demonstrates a fairly good correlation between the clinical complaints and the results of the dextrose tolerance test.

Certain features of the study may be brought out best by representative protocols. Chart 1 represents a patient who had a Billroth I resection. It shows that abnormal absorption of sugar and untoward symptoms do not depend on a direct connection between the stomach and jejunum. This is indirect evidence against the theory that sudden jejunal distention is the principal cause of symptoms. Chart 2 also demonstrates that symptoms may develop both shortly after the ingestion of sugar and after a latent interval. It indicates that abnormal absorption of sugar may persist for many years. Such abnormally rapid absorption is not restricted to patients who have been operated on for peptic ulcer. Chart 3 shows a steep curve, which represents the blood sugar levels following a high carbohydrate meal in a patient who had a total gastrectomy for carcinoma eight years previously. This observation has been made by others.[7] Charts 3 and 4 illustrate that individual susceptibility must play some role in the production of symptoms, since both show extremely steep curves with decided hyperglycemia but no reaction beyond sleepiness. Chart 5 shows the converse, because this patient showed early symptoms with the dextrose tolerance test although the blood sugar never rose to high levels. This patient learned to avoid sweets shortly after operation and was thus able to keep himself symptom-free in his daily life. Chart 6 represents an extremely susceptible patient who had learned to regulate his diet by avoiding sweets and eating frequent small meals. Note that the blood sugar levels after a meal rich in fats or proteins were little more than half of those following a carbohydrate meal. This emphasized the practical value to this patient of avoiding food with a high carbohydrate content.

COMMENT

There appear to be two distinct syndromes following gastric surgery which must be differentiated: one appearing shortly after the ingestion of food, the other occurring after a latent period of one hour or longer. Both types have been shown to occur in the same person. There can be little doubt that delayed symptoms are due in most instances to a demonstrable hypoglycemia.

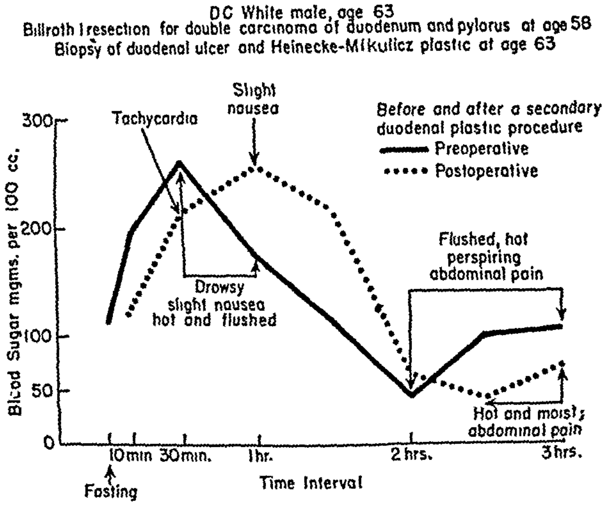

Chart 1—Oral dextrose tolerance tests (100 Gm) five years post operatively This patient showed symptoms both early and late after dextrose meals. He eats three meals daily, but has occasional mild epigastric pain which comes on several hours after meals and which is relieved by milk. Gastrointestinal roentgen examination shows no evidence of ulcer.

The cause and control of the other syndromes leave more room for disagreement. Hyperglycemia without regard to the rate of sugar absorption can hardly be the entire explanation, since a moderately elevated blood sugar level is well tolerated by many patients with diabetes. Furthermore, in a number of our cases the onset of symptoms preceded the rise of the blood sugar to its maximum level.

On the other hand, there are several important reasons why simple, sudden, mechanical distention of the jejunum is not a satisfactory explanation. Experimental work with distention of balloons at various levels in the gastrointestinal tract has failed to evoke symptoms comparable to the ones under consideration; this includes sudden distention of the upper part of the jejunum.[8] The syndrome has been shown to occur in patients who have no short-circuit from the stomach to the jejunum (as in a Billroth I resection). Finally, patients themselves notice the influence of different types of food and avoid concentrated sweets. The different effects can be observed in the same patient by the use of test meals rich in fat, protein or carbohydrates, as illustrated in chart 6.

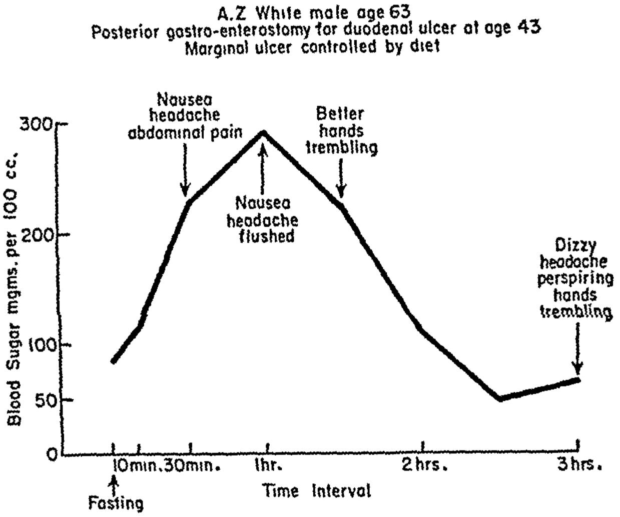

Chart 2—An oral dextrose tolerance test (100 Gm.) twenty years postoperatively exhibited an abnormal curve, in a patient with an intermittently active marginal ulcer. He experienced symptoms both in the hyperglycemic and hypoglycemic phases of the curve, with a symptom-free period between.

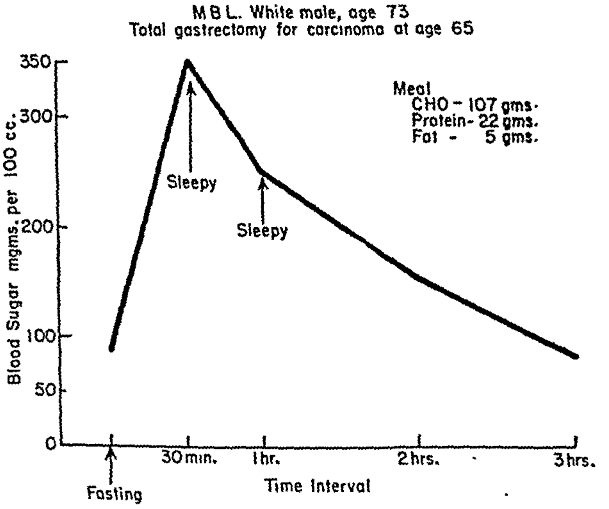

Chart 3.—High carbohydrate test meal eight years postoperatively; Drowsiness was the only symptom in a decidedly abrupt and pronounced hyperglycemia This patient eats three full meals daily and has no digestive complaints.

Whatever the exact mechanism, one may postulate a contributory role played by several different factors: (1) increased gastric motility (a relatively constant finding); (2) an abnormally rapid delivery of food into the jejunum, usually aided by a short-circuit around the duodenum; (3) failure of normal dilution of hypertonic solutions of sugar in the stomach as a result of the first two factors mentioned; (4) abnormally rapid absorption of sugar from the jejunum as the result of hypertonic solutions and a larger delivery of food than normal; (5) possible effects of distention of the jejunum by direct irritation of the mucosa by undiluted food, and (6) the susceptibility of the individual patient.

[8] Devine, J.: Personal communication to the authors.

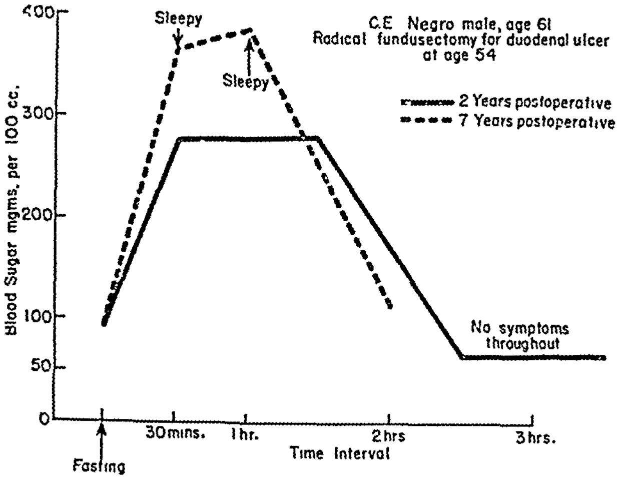

Chart 4.—Oral dextrose tolerance tests This patient is a stolid Negro who experienced nothing beyond drowsiness despite a decided hyperglycemia He eats three full meals daily and has no digestive complaints but spontaneously avoids sweets and meats

If various factors play a role, an attack on any one of them may help to alleviate symptoms. Thus, it is entirely logical to attempt to slow down gastric emptying by any means available, since this is bound to affect the other factors mentioned Since this may be difficult to accomplish, it is also reasonable to reduce the carbohydrate content and concentration of the feedings in an effort to slow down the rate of absorption of sugar and the possible irritative action on the jejunum.

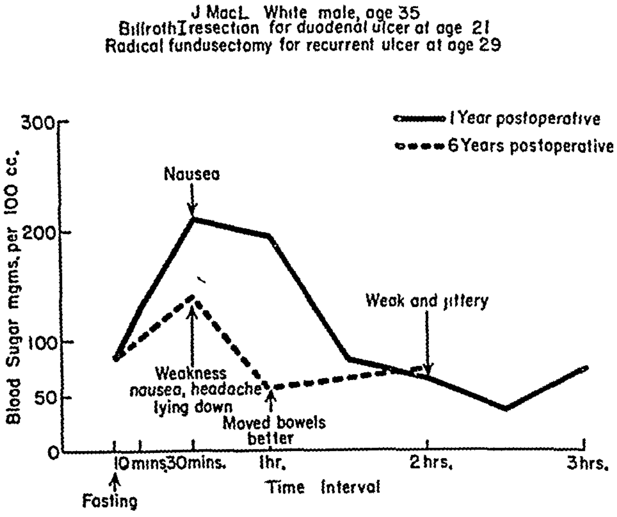

Chart 5.—Delayed hypoglycemia is shown in two oral dextrose tolerance tests (100 Gm) five years apart, in a patient who experienced both early and delayed symptoms This patient eats three full meals daily and has no digestive complaints, but he found out shortly after operation that he could not eat excessive sweets, pastries or custards and was nauseated by milk, consequently he avoids these foods because of their immediate rather than their delayed effect.

SUMMARY AND CONCLUSIONS

1. The present study confirms the belief that abnormal sugar absorption takes place in many patients who have had gastric operations. This abnormality consists of a rapid rise of blood sugar to high levels and a precipitous fall, often to hypoglycemic levels.

2. This phenomenon may be observed after a variety of gastric procedures, both for ulcer and for carcinoma, and may persist for years.

3. Unpleasant symptoms may occur shortly after the ingestion of a meal rich in carbohydrates, which is the hyperglycemic phase, or after several hours—the hypoglycemic phase.

4 The intensity of these reactions depends on the given patient's susceptibility.

5. Although the mechanism involved in the production of early symptoms is not yet clearly understood, smaller and more frequent feedings, with calories derived from fat or protein, are suggested as one means of controlling the symptoms. This is in accord with the observation that many patients who have had gastric operations appear unable to tolerate concentrated sweets well and tend to avoid them spontaneously. Test meals low in carbohydrates evoke reactions of lesser degree in susceptible patients.

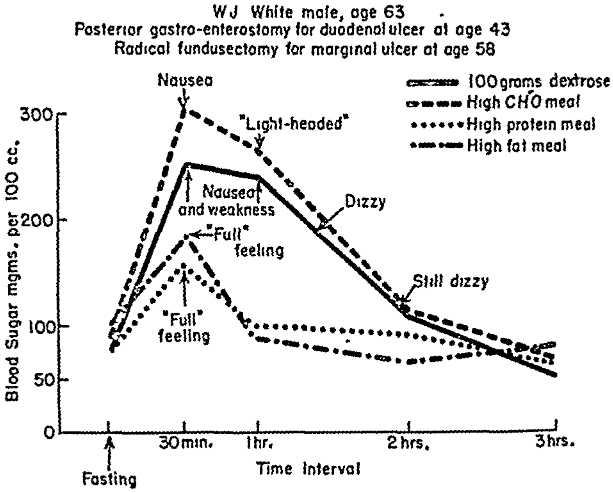

Chart 6 - Test meals five years postoperatively were given on successive days and, except for the dextrose meal, were of equivalent bulk The sharpest and most prolonged reaction came from the dextrose meal, the high protein and high fat meals, by way of contrast, gave the patient only a feeling of fulness, the same feeling which prevents his eating a complete meal.

6. The patient who has symptoms several hours after eating may require food to combat hypoglycemia.

7. It is believed that many patients who have submitted to gastric surgery can be benefited by the regulation of their carbohydrate intake.

ABSTRACT OF DISCUSSION

DR. H GLENN BELL, San Francisco: The question arose in reading this paper, whether Drs. Zollinger and Hoerr have a different type of patient in the East than we have in San Francisco. I have not seen the severe reactions that he has described I have seen some of the milder symptoms. They come on early in the postoperative course and may last for several months. It has been the practice to advise these patients that they should eat frequently and in small amounts. Symptoms have been explained as resulting from the dumping effect of the stomach directly into the upper jejunum, with a sudden dilatation of the jejunum. The study with the balloons in the gastrointestinal tract tends to discredit this idea. Tactfully, however, it does work. Since all patients are followed indefinitely, it is observed that these symptoms tend to disappear in a few months There are patients who have an idiosyncrasy for carbohydrates, particularly sugar, and so I have met patients of this type who have other surgical conditions outside of the gastrointestinal tract. When the surgeon tries to build these patients up with a high carbohydrate diet preparatory for surgical intervention, they say that they cannot take carbohydrates because they become nauseated, and some of them actually will vomit. If this same condition is present in a patient who had to have a gastric resection, I can see where they might have added postoperative difficulty.

Dr. Sidney A. Portis, Chicago: I could not follow Dr. Zollinger's line of thought when he was talking about the question of hyperglycemia and hypoglycemia in the same breath. In the early symptoms of this clinical condition, I don't think the question of hyperglycemia is involved at all. I consider the symptoms entirely due to a disturbed physiologic balance, which is associated with rapid emptying of the stomach and overdistention of the small intestine. I can, however, go along with him on the question of hypoglycemia. I reported in this section in 1944 that I thought there was a definite relation between the pain in ulcer and the levels of sugar in the blood. The pain which came on one to three hours after eating may be associated with a hypoglycemic phase. This also may account for the early morning pain long after the intake of food. This hypoglycemic phase can be completely abolished by the use of atropine and frequent feedings, particularly if atropine is given before bedtime. Vagotomy, as has been reported, completely abolishes the insulin response and does, from a surgical point of view, what one pharmacologically attempts to do with atropine. In 1944 I published a diet for an ulcer patient which was devoid of free sugar but allowed complex carbohydrates to remain in the diet. The explanation for the avoidance of free sugar was given at that time and needs no repetition here. The postdigestive hyperinsulinism with an intact parasympathetic nervous system can produce a hyperacidity, which may be responsible for the symptoms of which the ulcer patient complains.

Dr. Asher Winkelstein, New York: During the past twenty-five years there has been conducted a careful follow-up of the patients who have had a subtotal gastrectomy for peptic ulcer at the Mount Sinai Hospital. The postoperative symptomatology has been studied in four groups of symptoms after subtotal gastrectomy has been encountered. The first group is the group with recurrent ulcer (proved roentgenologically) and the presence of free hydrochloric acid. The second group has ulcer-like symptoms, including occasional hemorrhage, without free acid and with negative roentgenologic observations. In this group the symptoms are probably due to gastritis with erosions. A third group has symptoms which are chiefly intestinal. They have abdominal distention, cramplike pains, constipation and, rarely, diarrhea. In this group the symptoms are probably due to the dumping action, which is frequently cited as the explanation of all except ulcer symptoms after subtotal gastrectomy. The fourth is the group on which Dr. Zollinger has so ably reported. This group consists of patients who have dizziness, faintness, perspiration and weakness, usually occurring within the first hour after a meal. These patients learn to help themselves in two ways: (1) they eat solids at the beginning of the meal and (2) they restrict their dextrose intake. The late Dr. Glaessner studied with me in my gastrointestinal clinic a series of patients who had these symptoms after meals. We gave them 300 cc. of 50 per cent dextrose and studied the blood sugar curve every fifteen minutes for the next three hours. In the patients who had had symptoms spontaneously there also developed symptoms after the intake of this sugar at the time when there was a marked hyperglycemia. The patients often had blood sugar levels of 250 to 400 mg. per hundred cubic centimeters. This was characterized as hyperglycemic shock. Often, in addition to the dizziness, perspiration and faintness of these patients, mental symptoms developed. They became loquacious, disoriented and in some cases had alternate spells of laughing and crying. The neurologists may be interested in studying this hyperglycemic reaction in relation to the hypoglycemia which they institute in the therapy of certain mental diseases.

MODERN PHYSIOLOGIC CONCEPTS

Their Application to the Treatment of Disease of the Liver

JAMES F. WEIR, M.D.
Rochester, Minn.

Treatment of hepatic disease until recent years was largely symptomatic. Diets low in all constituents were prescribed to spare the diseased liver as much as possible. As ascites was often the first clinical manifestation of chronic hepatic disease, the attack was primarily against this by means of purges, restriction of fluid and salt and, in more recent times, the administration of acid-forming salts and organic mercurial diuretics. Undoubtedly much damage was done by the enthusiastic therapeutist. Little attention was given to methods of supporting the liver, and little was known of the factors leading to ascites. In the twenties attention began to be directed to the condition of the liver based on new knowledge of its physiology and the experimental production of hepatic disease. Since then progressive changes in therapeutic practice have occurred. Results remain difficult to evaluate, but a scientific clinical approach has been developed.

In an attempt at orientation in current conceptions of hepatic therapeutics the subject may be conveniently considered under the following headings: (1) current concepts of hepatic physiology; (2) experimental production of hepatic disease; (3) results of application of new data to clinical practice, and (4) criteria for evaluation of results of this application.

CURRENT CONCEPTS OF PHYSIOLOGY OF THE LIVER

The liver, which is the largest organ in the body, possesses remarkable reserve and regenerative capacity. Removal of 80 per cent of the organ in animals leaves a portion adequate to carry on necessary functions, and the liver rapidly regenerates. It regains normal size in six to eight weeks. The polygonal cell is the characteristic cell of the liver. The functions of the liver largely depend on this cell, which is the site of injury in pathologic processes. Each cell performs specific functions as part of the organ in addition to its own basic protoplasmic functions. The functions of the liver are many (more numerous than those of any other organized tissue) but they may be grouped under a few headings; namely, production of bile, detoxification and participation in general metabolism. While these functions of the liver are interrelated, nevertheless the seriousness of hepatic disease depends principally on the degree of impairment of its metabolic activities.

Carbohydrate Metabolism.—The liver stores ingested carbohydrate as glycogen, an easily available source of energy, though the amount stored varies greatly. Starvation rapidly depletes the stores of glycogen, but the liver seldom is devoid of it. On the other hand, as much as 20 per cent of the weight of the liver may be glycogen. When such an amount is present, it causes impairment of some of the functions of the liver. In addition to monosaccharides, glycogen may be formed from lactic acid produced in the muscles, from protein and from the glyceride of fat. This transformation

From the Division of Medicine, Mayo Clinic.

Read in a symposium on "Diseases of the Liver" before the joint meeting of the Section on Gastro-Enterology and Proctology and the Section on Pathology and Physiology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 5, 1946.

This paper and the succeeding papers by Dr. Osgood, Drs. Giansiracusa and Althausen, Dr. Capps, Captain Sborov and Dr. Barker, and Dr. Wilbur are part of a symposium of eleven papers on "Diseases of the Liver." The other six papers in the symposium will be published in The Journal next week.

occurs chiefly if not wholly in the liver and is particularly prominent in carbohydrate starvation. When adequate carbohydrate is available, protein will not be called on to supply carbohydrate for fuel. This function is known as "the protein sparing function of carbohydrate." When excess glucose is available, it is converted to fat and is deposited in the fat depots. There is no evidence that the reverse is true: namely, that fat is converted to glucose when the supplies of the latter are low. Under this condition fat will be mobilized and partly broken down by the liver to ketone bodies. Carbohydrate inhibits this breakdown (antiketogenic activity).

The liver converts glycogen to glucose to maintain a certain level of glucose in the blood and to supply the needs of body tissues. This regulation of blood sugar is an important function of the liver, although it is modified by many substances and processes of a fundamental nature, such as the endocrine factors. Thus, the liver stores glycogen when the blood sugar is increased after ingestion, and reconverts glycogen to glucose when the body requires it. In other words, the glycogen stores are mobile.

Removal of the liver in animals produces a characteristic train of symptoms accompanied by a progressive hypoglycemia. Dextrose is specific for these manifestations, but the administration of increasing amounts, up to 1 Gm. per kilogram of body weight per hour, is required. Then another group of symptoms leading to death of the animal appears; for these the administration of dextrose is of no avail, and as yet no explanation for their occurrence is known.

Glucose furnishes glucuronic acid for conjugation with phenol derivatives and acetyl groups for acetylation of para-aminobenzoic acid and sulfanilamide. The rate of these processes of detoxification is based on the concentration of glycogen in the liver. The glycogen stores in the liver are decreased by various toxic agents, such as chloroform, and anoxemia and deposition of fat follow. Livers with adequate stores of glycogen are less susceptible to these toxins. Animals with a damaged liver require a higher level of blood sugar than normal animals before glycogen will be stored. Amounts of dextrose that will maintain the blood sugar at normal levels in a hepatectomized animal will not cause a damaged liver to store glycogen.

Protein Metabolism.—The products of protein digestion come to the liver as amino acids, which are worked over and from which new proteins required for the maintenance of tissues and normal growth are formed. The liver is concerned in the elaboration and maintenance of the plasma proteins, among which are albumin, globulin, fibrinogen and prothrombin. A portion of the newly synthesized protein is stored in the liver and is extremely labile. It can be mobilized more quickly and can be utilized more easily than proteins of other tissues. The liver appears to regulate the supply of proteins to the tissues by regulation of the plasma proteins. Protein is also necessary for the formation of cholic acid, and certain proteins accelerate its formation. The liver is the major site of deaminization; the nitrogenous portion of the amino-acid molecule is converted to urea and excreted; the remainder of the molecule is metabolized as d-glucose and fat.

Fasting decreases the protein content of the liver, and fat is deposited; if fasting is long continued, hypoalbuminemia develops. In disease of the liver the level of the serum albumin is often considerably lowered, the concentration of serum fibrinogen is decreased and the formation of prothrombin is affected. These changes apparently result from decreased ability of the liver to fabricate these proteins. A liberal protein diet, which insures adequate stores of labile protein in the liver, protects the organ from the effects of various toxins, such as chloroform, carbon tetrachloride, arsenic and selenium. That this is not due to the formation of glycogen from protein is indicated by the fact that a liver high in glycogen and fat but low in protein is susceptible to injury from chloroform. How protection is afforded is uncertain. According to one theory sulfur is readily available in certain amino acids for combination with toxins; another theory states that protection is due to the lipotropic effects of amino acids. There is some evidence that the quality of proteins is important. Observations on dogs with Eck fistulas have shown that meat or its extractives produce intoxication, whereas milk, bread and cereals do not. Bollman and Mann[1] have shown on dogs with cirrhosis secondary to obstruction or to administration of carbon tetrachloride that substitution of meat for a carbohydrate diet led to the formation of ascites.

Metabolism of Fat.—Fat circulates in the blood as neutral fat (glyceride), phospholipids and cholesterol esters and exists in the liver in these forms. It originates from the ingestion of fat, mobilization from the depots and synthesis of fat by the liver from carbohydrate and protein. The liver harbors fat in varying amounts but is not a storehouse for fat. Fat is constantly being mobilized to the liver, worked over and moved out. Phosphorylation is an important part of this metabolic process and, although the phospholipid content of the liver varies little normally, the rate of phospholipid turnover does vary. In the liver there may be rearrangement of the fatty acids in the molecules and there may be limited shortening or lengthening of the fatty acid chain and introduction of double bonds into saturated chains. The liver also is the principal if not the only site of formation of ketone bodies.

The amount of fat in the liver is fairly constant when the intake of carbohydrate and protein is adequate; it averages from 2 to 4 per cent of the weight of the liver. On hunger the liver gives up fat, but the fat content is constantly replenished from the fat depots. Under certain conditions 50 per cent of the liver by weight may be fat, and this condition produces impairment of some hepatic functions. A liver containing increased amounts of fat is particularly susceptible to the effects of hepatic toxins. Although a liver which is high in glycogen stores is resistant to these toxins, one in which stores of both glycogen and fat are high is susceptible. Increase in the rate that fat is supplied to the liver occurs during ingestion of a high fat diet, during starvation and after the administration of the antiketogenic fraction of the anterior part of the pituitary. Decrease in the rate at which the liver disposes of fat occurs as a result of the action of various toxins, such as halogenated hydrocarbons and phosphorus, feedings of cholesterol, pancreatectomy and deficiency of choline. Experimentally fatty livers have been produced by these and other means. They differ somewhat in response to lipotropic agents and possibly in the type of the fat. In the human being, pathologic accumulations of fat occur particularly in the so-called alcoholic fatty liver. Though few analyses of the fat in the liver have been made in human beings, such evidence as is available indicates that the increase is chiefly in the neutral fat fraction.

Lipotropic Factors.—A lipotropic substance is one which prevents the deposition of fat in the liver or increases the rate of its removal. The term lipotropic substance was originally applied to lecithin and its effect in preventing the fatty infiltration of the liver of depancreatized dogs which were being maintained on insulin. Choline was later shown to be the constituent of lecithin that was active in this respect. Other agents with lipotropic action have been identified: lipocaic, inositol and certain amino acids.

Choline participates in a reversible transmethylation process. It furnishes a methyl group for homocystine, which originates in the diet or is present in the tissues from previous demethylation of methionine, to synthesize methionine. On the other hand choline is formed from nitrogenous precursors, such as amino-ethanol, amino-acetic acid and betaine, by the addition of a methyl group supplied by methionine. Thus both choline and methionine contribute methyl groups in these metabolic processes. Some of these methyl groups go to the formation of creatine and are then lost to the bodily metabolic economy. Though choline can be synthesized, there seldom is a deficiency of it, as it is supplied in the diet as free choline or phospholipids. Choline deficiency may be interpreted in broader terms; namely, as an inadequate supply of methyl groups. The lipotropic action of methionine is indirect: it supplies methyl groups for the synthesis of choline; and protein is lipotropic through its methionine content.

The lipotropic action of choline is due to its promotion of synthesis of phospholipid in the liver as well as in the intestine. This synthesis is necessary for the transportation of fat from the liver, and the effect is chiefly on the neutral fat fraction. The methyl groups apparently are not necessary for, and do not take an active part in, the process of phosphorylation; the whole molecule participates as a unit.

Vitamins.—The liver is intimately associated with the metabolism of vitamins. In disease of the liver this power may be disturbed by failure of proper absorption, failure of storage in the liver and defects in intermediary metabolism. Jaundice with deficiency of bile salts in the intestine gives rise to failure of adequate absorption of the fat-soluble vitamins. Though vitamin A is absorbed, carotene is not. The liver is the only important site of conversion of carotene to vitamin A, and it stores vitamin A. Moreover, the stores can be depleted rapidly. In cirrhosis the vitamin A content of the liver is only 10 per cent of normal. The defective dark adaptation of cirrhosis is little benefited by the administration of vitamin A. Vitamin D also is largely stored in the liver, and this storage can occur in the presence of jaundice if vitamin D is given parenterally. However, the action of vitamin D is less efficient in the presence of hepatic disease than at other times. Osteoporosis may occur in cirrhosis, but vitamin D is not effective in its control. Vitamin K is necessary for the formation of prothrombin by the liver. A deficiency of vitamin K may arise from inadequate absorption, as in acholia. However, numerous water-soluble analogues are available and can be used when a deficiency arises, with excellent results. Faulty utilization of vitamin K occurs when hepatic damage is sufficiently extensive. The liver is rich in known and unknown factors of the vitamin B complex, acting as a storehouse for these substances. Several of these play an important part in the oxidation of carbohydrate and also in the synthesis of fat from carbohydrate and protein by participation in enzyme systems. Extra intake of carbohydrate may exhaust these, and this suggests the advisability of an extra intake of the vitamin B components when large amounts of carbohydrates have been given. Neuritis and pellagra have been reported in varying frequency in cirrhosis, but it is uncertain how much the disease of the liver may contribute to the production of these deficiencies. Fundamentally, the disturbances of metabolism of vitamins in hepatic disease are intrinsic; failure of intake and absorption are secondary influences. The changes induced as a rule are little influenced by administration of the vitamins.

The liver is a storage depot for the erythrocyte maturing factor. There is some evidence that the amount of this factor stored in chronic disease of the liver is decreased. How significant this is in the development and treatment of macrocytic anemia in cirrhosis is uncertain.

Ascites.—Ascites develops frequently in both acute and chronic liver disease, and the explanation for the process is not clear. Portal hypertension has long been considered the most important causative factor. The presence of portal hypertension, however, cannot be demonstrated in all cases. Lowering of the serum proteins, disproportionate decrease in the serum colloid osmotic pressure, dietary factors, disturbance of ability of the liver to handle water and altered permeability of capillaries are other important influences in the occurrence of this manifestation. Because of some of these factors much has been written concerning the oral or intravenous use of various protein hydrolysates for the control of ascites. Theoretically, permanent benefit will come only when the liver has recovered sufficiently to maintain adequate concentration of proteins in the plasma.

More recently, Ralli and associates[2] have reported the presence of increased amounts of an antidiuretic substance, apparently produced by the hypophysis, in the urine in cases of hepatic disease with ascites. The diseased liver apparently fails to destroy this antidiuretic substance. With improvement in the function of the liver, destruction of this substance is accomplished and spontaneous diuresis occurs. Confirmation of this work will be awaited with interest.

EXPERIMENTAL PRODUCTION OF HEPATIC DISEASE

It is well known that a variety of agents are capable of producing degeneration and necrosis of liver cells. The continued or repeated action of these agents leads to the development of changes characteristic of cirrhosis; namely, degeneration, necrosis and regeneration of cells and proliferation of fibrous tissue. Fatty livers and eventually cirrhosis develop in dogs after pancreatectomy and maintenance with insulin. In recent years emphasis on the relation of nutrition to the production of experimental cirrhosis has been increased. Patek and Post[3] suggested that there may be a correlation between the dietary deficiency encountered in alcoholism and cirrhosis. Connor[4] emphasized the importance of fatty livers in the development of cirrhosis in diabetes and in chronic alcoholism. He and his associate[5] found support for this hypothesis in the production of cirrhosis in dogs by a high fat diet and the administration of alcohol and by the feeding of a high fat diet alone. György and Goldblatt[6] observed hepatic injury in young rats kept on a diet devoid of a portion of the vitamin B complex. Rich and Hamilton[7] produced cirrhosis in rats, as did Spellberg and Keeton[8] in guinea pigs and rabbits, on a nutritional basis. From the various studies it is evident that diets moderately high or high in fat, low in protein and deficient in choline will produce changes in the liver. These can be prevented by the administration of choline and yeast, choline and cystine or choline alone. Extra cystine in the diets of rats has accentuated the development of cirrhosis. Lillie, Daft and Sebrell[9] produced cirrhosis in rats by low protein, low fat, choline-deficient diets with cystine added. Cirrhotic changes were prevented by the administration of choline, casein and methionine singly or in combination; their prevention can be explained on the basis of the lipotropic action of the supplements given. Most work has indicated that cystine aggravated the hepatic changes, particularly necrosis, which was often accompanied by hemorrhages. Hemorrhages also were encountered in the kidneys of young rats. György,[10] however, stated that choline was more effective from a protective point of view when cystine was also given. He pointed out that in experimental studies in which choline alone prevented hepatic injury the diets contained a certain amount of cystine.

[3] Patek, A. J., Jr., and Post, J.: Treatment of Cirrhosis of the Liver by a Nutritious Diet and Supplements Rich in Vitamin B Complex, J. Clin. Investigation **20**: 481-505 (Sept.) 1941.

Although choline prevents infiltration of the liver with fat from high fat-low protein feeding, it only partially prevents the changes induced by cholesterol feeding or by the administration of pituitary extracts. Lipocaic and possibly inositol apparently are more effective in the prevention of hepatic changes under these circumstances, though this is still subject to discussion. Choline has little effect in preventing lipoid deposition in the liver on injury from chloroform or carbon tetrachloride but does increase the rate of disappearance of fat during recovery. Once cirrhosis has been produced by these dietary methods, choline and methionine supplements aid regeneration of the liver cells, but the fibrosis is unaffected. Cirrhotic livers produced by diet are characterized by the presence in the phagocytic cells of ceroid, which does not disappear on recovery following high protein diet or administration of methionine and choline supplements. It has not been observed in cirrhotic livers of human beings. These dietary experiments are essentially of two types: (1) short term, in which fatty livers are prevented or are corrected by doses of choline and methionine and (2) long term, in which cirrhosis also results, and in which the fibrosis is not cured by the lipotropic agents.

RESULTS OF APPLICATION OF NEW DATA TO CLINICAL PRACTICE

The modern physiologic concepts previously mentioned, on which present-day practice is based, indicate that a liver which contains adequate stores of glycogen, protein and vitamins and normal amounts of fat, and which can maintain these stores because the intake of essential food is sufficient manifests the greatest resistance to toxins. Furthermore, these concepts indicate that after hepatic disease is established an increased intake of carbohydrate and protein is necessary to maintain the stores in the liver and to promote regeneration. The experiments of Opie and Alford[11] in 1914 led to the application of a high carbohydrate diet in clinical practice. The work of Ravdin and Whipple and their co-workers[12] led to the use of increased amounts of protein. Excessive deposition of fat appears characteristic of many hepatic diseases and increases the susceptibility of the liver to further injury. The advisability of a low intake of fat is not settled. A diet low in fat is difficult to prepare in an appetizing manner that will appeal to the patient, who often has anorexia and even nausea. A diet low in fat tends to be low in calories, fat-soluble vitamins and essential unsaturated fatty acids. Furthermore, there is no good evidence that moderate amounts or even large amounts of fat in the diet are harmful if given with adequate protein and carbohydrate.

In the application of the physiologic data to hepatotherapy an evolutionary process has been noticeable first, in the institution of a high carbohydrate intake and then, in the addition of protein to the diet, at first in moderate amounts and then in large amounts. Later supplementary vitamins, yeast and extract of liver were added to the diet, and finally the lipotropic agents, choline and methionine. The fundamental principle in treatment has been and still is the administration of these diets. It is essential that the food prescribed be eaten. Secondary considerations occur when patients cannot take adequate amounts of the food or when specific results are desired. Thus, tube feeding and intravenous infusions of dextrose, preparations of amino acids, plasma, serum or whole blood, as well as the various dietary supplements have been used. Numerous papers have been published on the results of the use of these programs in hepatitis and cirrhosis. In 1936 Jones[13] reported decided lowering of the mortality rate in 32 cases of hepatic insufficiency following the use of a high carbohydrate diet which was frequently supple-

mented with solutions of dextrose given intravenously. In 1943 Ravdin and associates[12b] reported on the use of high protein intake. More recent studies include the report of Barker, Capps and Allen,[14] who in a careful study of 421 cases of infectious hepatitis in the Mediterranean theater of war were impressed with the value of a high protein, high carbohydrate, low fat diet. They gave as much as 200 Gm of protein daily, chiefly as beef, milk and cheese. In their opinion it was uncertain whether the chief benefit was from the high protein, high carbohydrate, low fat diet or from the better caloric intake. The same authors[15] reported on 76 cases of chronic infectious hepatitis. One group of their patients received a diet of 250 Gm. of protein, 350 Gm. of carbohydrate and 40 Gm. of fat and were kept at complete rest in bed. The other group was given a similar diet except for a reduction in the protein to 85 Gm., and they were kept at only moderate rest in bed. The first group progressed better. The authors could not determine whether this greater progress was due to the increased amount of protein, calories or rest in bed.

The first report of the use of methionine in toxic hepatitis is that of Beattie, Herbert, Wechtel and Steele.[16] They treated a soldier who had accidentally swallowed 30 to 40 cc. of carbon tetrachloride A casein digest and methionine were cautiously given intravenously. The clinical symptoms improved and the size of the liver decreased. Recurrence of symptoms and enlargement of the liver on the third day were controlled by similar treatment, and the patient recovered. Reports by Eddy,[17] Peters and associates,[18] and Beattie and Marshall[19] have followed. Some investigators[20] have reported no benefit from the addition of 5 Gm. of methionine to the diet in cases of infectious hepatitis. Hoagland and Shank[21] studied the effects of giving 5 Gm. of methionine daily in 16 cases, 5 Gm. of choline daily in 25 cases and of crude liver extract in 34 cases of infectious hepatitis. None of these procedures produced any changes in the duration of illness, weight curve or those functions of the liver which were studied, which were different from those in a control group.

Patek and Snell and their associates[22] were the first to report lessened mortality and morbidity in cirrhosis after treatment by highly nutritious diets with the addition of vitamins. Reports on the use of choline or methionine in the treatment of cirrhosis have been made by Brown and Muether,[23] Yater,[24] Russakoff and Blumberg,[25] Barker,[26] Wade,[27] Beams[28] and Morrison.[29]

From these data it is impossible adequately to evaluate the benefit of the individual factors, such as intake of calories, protein or carbohydrate, and the effects of vitamin supplements or lipotropic factors, as all were used in various combinations and to varying extents. Other factors, such as ability of the patient to take the prescribed diet, cessation of alcoholic intake and degree of rest enforced, enter the picture. However, all workers have been more or less agreed that adequate caloric intake, especially of proteins and carbohydrates, is a most important factor.

CRITERIA FOR EVALUATION OF RESULTS OF APPLICATION OF NEW METHODS

In the clinical application of these physiologic concepts certain more or less obvious but fundamental facts must be kept in mind. Some of these will be considered in detail.

Nature of the Disease.—Because of its structure, the liver is limited in the way it will respond to injury. Knowledge of etiologic factors in hepatic disease is as yet circumscribed. Various factors may lead to acute hepatitis, such as numerous toxins and the viruses of infectious hepatitis and serum jaundice, but many cases of acute hepatitis occur, in which the etiologic factor is unknown. Nevertheless, the course of acute hepatitis in many cases is self limited, and full recovery occurs. The pathogenesis of cirrhosis is obscure and will remain so until information is obtained concerning its early stages. Though the etiologic role of alcohol is uncertain, the cessation of its use might play a significant part in recovery. However, evaluation of this factor is difficult. Many investigators claim that cirrhosis is the late stage of fatty infiltration of the liver. This may be correct in many cases, but it is not yet proved that cirrhosis always begins in fatty livers. Spontaneous remissions of symptoms occur in cases in which hepatic insufficiency is associated with large, perhaps fatty, livers and also in cases of cirrhosis. These remissions make it more difficult to evaluate any therapeutic procedure correctly. It is generally agreed that the enlarged liver responds better to therapy and carries a more encouraging prognosis than does cirrhosis in the small liver. Treatment of cirrhosis does not affect the fibrosis. Benefit will come only in promoting the efficiency and regeneration of parenchymal cells. The earlier treatment is instituted the better the results should be. Undoubtedly in many cases an irreversible stage is reached, after which treatment is unavailing. In some cases treatment is unavailing even though started early. In general, treatment must consist largely of attempts to arrest the progress of hepatic disease by facilitating functional activities, repair and regeneration, and by decreasing the vulnerability of the liver cell.

Possible Influence That New Methods Could Have on Course of Liver Disease.—In acute stages of hepatic diseases, for a priori reasons the so-called liver diet cannot be used in a preventive way unless the dietary standards of the nation are to be changed. From a preventive point of view, however, persons exposed to industrial chemicals which are hepatotoxic, those receiving therapeutic agents which may have similar action and those who have biliary or pancreatic disease should have this diet. Some attempts have been made along this line. Beattie and Marshall[10] recently reported lessened frequency of hepatic injury in arsenical treatment of syphilis after the addition of casein and cystine or methionine to the diet. From a curative point of view, the liver diet could aid regeneration in toxic and infectious hepatitis and in cirrhosis. However, in advanced cirrhosis in which the condition approaches that of the Eck fistula, from a vascular point of view proteins of a certain quality may be detrimental. In less advanced cases, proteins of a certain quality may be conducive to the formation of ascites. These effects have been observed in the experimental animal, but whether they occur in the human being is not known.

Relation of Experimental Disease to Human Disease.—Types of experimental hepatic disease include those produced by various hepatotoxins, those resulting from pancreatectomy and from maintenance of the animals with insulin and those due to diets deficient in certain respects. Infiltration of the liver with fat probably plays a role in all of these. Acute toxic hepatitis of human beings resembles that of animals, but it is seldom that the toxins used for producing cirrhosis in animals play a causative role in the cirrhosis of human subjects. The fatty livers of depancreatized dogs maintained on insulin develop while the animals are on a diet of lean meat, sucrose and no fat. Infiltration of the liver with fat, and occasionally cirrhosis, are seen in certain cases of diabetes and chronic pancreatitis among human beings; but to date my colleagues and I have not been able to demonstrate fatty infiltration of the liver or cirrhosis in cases in which partial or total pancreatectomy has been performed. These factors are at best infrequent causes of cirrhosis in human beings.

Distorted diets, such as those used to produce experimental cirrhosis, would seldom be followed by human beings. Nutritional deficiencies encountered clinically usually are multiple, whereas restriction of a single dietary essential has usually been employed to produce a deficiency syndrome in experimental animals. Experimental cirrhosis also differs from that encountered clinically by the presence of ceroid. There is some circumstantial evidence that deficient diets may play a part in the cirrhosis of human beings. The disease occurs with higher incidence in certain regions where nutrition is poor and nutritional diseases are endemic. The role of alcohol is uncertain and remains debatable. The diet of alcoholic addicts is deficient, particularly in proteins and vitamins, and the disease of the liver may be a manifestation of this deficiency, as are other nutritional defects. However, only about 5 per cent of persons with alcoholism show hepatic damage, and in many cases of cirrhosis seen at necropsy no history of alcoholism is obtained. Some further evidence that dietary deficiency may cause hepatic disease in human beings is the incidence of liver disorders among the nutritional disturbances encountered in the repatriated prisoners of war, whose limited diet was largely carbohydrate. On the other hand, hepatic disease is encountered infrequently in the undernutrition of anorexia nervosa, of long-continued organic gastrointestinal disease or from prolonged use of eccentric diets. Moreover, most patients who have cirrhosis of the liver are well nourished at the onset of the disorder. Furthermore, the fact that the fatty liver with varying degrees of hepatic insufficiency or cirrhosis in human beings may show improvement or remission of symptoms on modern dietary management is no indication that a dietary deficiency is etiologically significant. The chemical changes as well as some deficiencies encountered in cirrhosis could as likely be secondary manifestations depending on the inability of the liver to perform its normal metabolic processes. At present the question whether impaired nutrition is a factor in the production of cirrhosis in man must be left in abeyance for continued investigation.

Lipotropic Substance in the Therapeutic Program.—Choline is found in large amounts in liver, white wheat flour, polished rice, skimmed milk, dried yeast, soybean meal, peanut meal, cheddar cheese, butter and eggs. The methionine content of the proteins of milk, eggs, meat, fish and whole corn varies from 3 to 4 per cent by weight. The daily requirement of methionine is about 3 Gm. A diet of 120 Gm. of protein, 500 Gm. of carbohydrate and 60 Gm. of fat contains about 3.5 Gm. of methionine. Diets now advocated for disease of the liver have a content of 100 to 200 Gm. of protein, 300 to 500 Gm. of carbohydrate and 50 to 175 Gm. of fat. Such diets obviously contain adequate amounts of choline and methionine. From this there would appear to be little rationale in giving these as supplements, except to patients who are unable to maintain an adequate dietary intake. The published results of the use of these supplements have not contained convincing evidence of their effectiveness. Many studies have given negative results, and most of the others have been inconclusive.

Necessary Criteria.—Criteria for judging the benefit derived from the various dietary procedures have varied. Some studies have been based on the clinical improvement, and the validity of the results depended on the judgment of the investigator. Duration of hospitalization, mortality rate, severity of disease and depth of jaundice, the time required for jaundice to subside so that an arbitrary level of serum bilirubin near normal was obtained, weight curve, duration of anorexia, changes in size and tenderness of the liver, duration of biliuria and frequency of relapses were factors on which judgment of benefit was based. In some studies no controls were established. In others, groups of patients who received a therapeutic agent which was not given to the control group were studied. Some of the patients who served as controls, however, presented other variables. In general, in cases of toxic or infectious hepatitis in which adequate controls were established negative results were obtained when choline or methionine were added to the program of treatment. In cirrhosis it is extremely difficult to establish adequate controls. The chronicity of the disease, variability of the size of the liver and spleen, presence or absence of jaundice and its intensity, presence or absence of ascites and spontaneous remission of symptoms have much influence on the results of any treatment. Changes in the various biochemical disturbances induced by therapeutic agents have been utilized in the evaluation of results but are not too satisfactory. Blood sugar usually is normal and hypoglycemia is a rare occurrence in cirrhosis, whether the glycogen content of the liver is normal or abnormal. The amount of fat in the blood may be normal, increased or decreased, but little is known of variations in the content of fat in the liver. It is not known whether an increased quantity of fat in the liver is due to increased mobilization from the depots of fat to the liver or decreased ability of the liver to work fat over and move it out, or to both factors. Lipotropic agents have little effect on an abnormal level of fat in the blood in cases of cirrhosis. Chemical studies of the fat content of the liver before and after the use of lipotropic agents have not been made, nor has a study of the rate of turnover of lipoids with radioactive phosphorus or other methods. The concentration of proteins in the blood is often decreased, particularly in the more advanced stages of the disease, and responds poorly to the increased administration of protein or to other therapeutic agents. When manifestations of vitamin deficiencies occur, administration of extra amounts of these factors often fails to give improvement. These evidences of resistance to therapy may indicate approach to the stage of irreversibility, but absence of measurable improvement does not necessarily mean that high caloric intake, particularly of carbohydrate and protein, may not be beneficial.

SUMMARY AND CONCLUSIONS

Modern treatment of hepatic disease has developed from the application of advances in knowledge of the physiology of the liver and from the results of experimental production of hepatic disease While the known functions of the liver are many and are interrelated, the seriousness of hepatic disease depends largely on impairment of the metabolic activities Evolution of the present treatment of hepatic disease has been largely along nutritional lines and has included the step by step addition of high intake of carbohydrate, then proteins and vitamins and, finally, lipotropic agents.

In the clinical application of the newer data of physiology, it is important that adequate controls be established. This is advisable not because the experimental data may be inaccurate but because they are in the borderline zone of advancing knowledge and cannot necessarily be viewed in their proper perspective at the present time. It is essential that the varying nature of the disease, together with such factors as cessation of alcoholic intake, degree of rest and ability of the patient to take the prescribed nutritive elements, as well as the possible influence of the dietary factors themselves, be constantly considered from a preventive and curative point of view. Evidence indicates that the high caloric intake, particularly of carbohydrate and protein, has been a distinct advance. The question of intake of fat remains unsettled. Administration of certain of the vitamins is probably advantageous. Lipotropic agents were hailed on theoretic grounds to be potentially important adjuncts, but experience to date has not substantiated this supposition or at best has only been suggestive of it. Absence of measurable results, however, does not necessarily mean that some benefit may not be obtained.

INTERPRETATION OF LIVER FUNCTION TESTS

EDWIN E. OSGOOD, M.D.
Portland, Ore.

Since a comprehensive discussion of liver function tests would require much more time than is available in this symposium, this article is limited to a presentation of the indications for doing the tests, of specific recommendations of the most satisfactory technics of certain principles and limitations in their interpretation and of references to the most recent authoritative literature. Those interested in a more detailed discussion may consult several excellent recent reviews.[1]

From the point of view of an internist teaching both physical and laboratory diagnosis, I want to emphasize that liver function tests, in fact all laboratory tests, are a valuable supplement to but no substitute for a well taken history and a thorough physical examination. The intelligent interpretation of the tests depends on an understanding of the underlying physiologic principles as outlined in the preceding discussion,[2] of the common sources of error in the methods[3] and of the

(Footnote 3 continued on next page)

skill and reliability of the persons collecting the samples and doing the tests.

Table 1 lists the symptoms and signs which indicate the desirability of liver function tests. Table 2 gives the liver function tests arranged in four groups. When any of the symptoms or signs listed in table 1 are present the tests listed in group *A* of table 2 should be performed. If any of the tests in group *A* give abnormal results or if the symptoms and signs suggest hepatocellular damage, the tests in group *B* of table 2 should be performed. If these indicate severe hepatocellular damage the tests in group *C* are worth while, not so much for diagnosis as for evaluation of the severity of the damage, since this group of tests gives abnormal results only in the severest diffuse impairment of function. If tests in group *A* or *B* are positive and a diagnosis has still not been reached, the more difficult and time-consuming tests listed in group *D* may add useful information provided facilities are available for performing them. However, these tests give abnormal results in many diseases in which the liver and biliary tract are not involved.

TABLE 1.—*Indications for Liver Function Tests*

- Jaundice
- Enlarged liver
- Tender liver
- Small liver
- Nodular liver
- Spider nevi
- Light or dark stools
- Deep amber urine
- Fetor hepaticus
- Anorexia
- Pruritus
- Nausea or vomiting
- Fatty stools
- Flatulence
- Splenomegaly
- Dietary deficiency
- Alcoholism
- Hyperthyroidism

The second column in table 2 gives the specific information sought for in performing the test. The third column lists only simple tests which should be available to every physician. These occasionally give misleading results, so when the results fail to check with the rest of the evidence or when the facilities of well equipped laboratories are available, the tests listed in the last column should be performed as checks or as the preferred technic. When two or more tests for the same purpose are listed in the same column the first is the simpler and more useful for screening purposes, and the last is the more reliable. The footnote numbers refer to the most useful articles on the technic but not necessarily to the original description, which will be found in the references cited.

Table 3 outlines the only classification of jaundice which, in my opinion, it is possible to make by laboratory methods. It includes the normal values and typical results of only the simplest recommended methods. Clinical and laboratory experience and careful study of the literature have failed to reveal any test which will differentiate reliably the jaundice of intrahepatic disease from the jaundice of extrahepatic obstruction. Each type of jaundice may occur without hepatocellular damage, and hepatocellular damage may occur in the absence

of jaundice or in association with the laboratory results typical of any one of the types of jaundice listed. Therefore, notwithstanding the widespread use of the term, it seems wise to accept the facts, discard the term hepatocellular jaundice and speak of patchy or diffuse hepatocellular damage without jaundice or with latent, partial obstructive, complete obstructive or hematogenous jaundice, as the case may be at that particular time in that particular patient.

Table 4 shows typical results of the simpler tests useful in evaluating the functional status of the characteristic cell of the hepatic parenchyma in health and in patchy and diffuse disease of the liver. It clearly reveals the limitations of these tests which are due to the tremendous reserve and the great regenerative capacity of the liver. Until this reserve and any functional regenerated cells are reduced to about 20 per cent of those in the normal liver, patchy lesions may show no evidence of impairment to liver function tests, and even the most extensive destruction by patchy lesions seldom shows more impairment to function tests than does mild diffuse damage. The tests are arranged roughly in the order of decreasing sensitivity. Since the tests in the lower half of table 4 are positive only in severe, diffuse hepatocellular damage, such as typically occurs in association with the pathologic picture of acute or subacute hepatic necrosis, they are of value not for diagnosis but for prognosis, guiding therapy and evaluating the severity of damage, in cases in which the tests in the upper half of the table are strongly positive. Failure to appreciate this has led many physicians to discard them as of no value.

TABLE 4.—*Classification of Hepatocellular Damage*

		Patchy		Diffuse	
Tests	Normal	<80%	>80%	Mild	Severe
Sulfobromophthalein, 5 mg./Kg. dose 30'	<5%		Trace—15%		>15% retention
Thymol turbidity	0 to 4 units		5 to 10 units		11 to 35 units
Hippuric acid after 6 Gm. sodium benzoate	4.2 to 5.9 Gm./4 hr.		3 to 5 Gm./4 hr.		0 to 3 Gm./4 hr.
Galactose tolerance after 40 Gm. orally	Under 3 Gm./5 hr.		2 to 5 Gm./5 hr.		Over 5 Gm./5 hr.
Prothrombin time 24 hr. after menadione 2 mg. intramuscularly	Normal		Improves		No improvement
Hypoglycemia	Absent		Slight or absent		Pronounced
Tyrosinuria	0		0		+ to ++++

The sulfobromophthalein sodium test is of most value in the nonjaundiced patient, as it is seldom negative in a person who has clinical icterus. A high concentration of urobilinogen in the urine in the absence of complete obstructive or hematogenous jaundice also suggests hepatocellular damage. Although the thymol turbidity and cephalin flocculation tests are tests for an abnormal lipoglobulin and failure of protection of normal gamma globulin by an adequate amount of normal albumin, respectively, these flocculation tests are probably the most sensitive and generally useful tests in calling attention to the probability of intrahepatic disease. The hippuric acid test is probably the most useful in the evaluation of the severity of moderate degrees of impaired hepatic function when impaired renal function, which commonly is associated with severe impairment of the liver's function, is excluded by a simultaneous phenolsulfonphthalein test.[3n] The galactose tolerance test is the most useful test for evaluating the course of severe, diffuse damage to hepatic cells.

The more frequently encountered groups of causes of the different types of jaundice are listed in table 5, and those of the different types of hepatocellular damage in table 6 with the commoner causes at the top and the less common causes at the bottom of the columns. Not only is there considerable overlapping of causes, but many patients may exhibit two of them at the same time. Furthermore, these lists are incomplete; there are many subdivisions to many of the groups, and there is evidence to suggest that there are diseases of the liver which are as yet unnamed and undescribed. More complete lists will be found in the reviews cited.[1] The diagnoses of some of these diseases are discussed in more detail in subsequent papers in this symposium.

TABLE 5.—*Common Causes of Jaundice*

Latent	Obstructive		
Jaundice	Partial	Complete	Hematogenous
Early, mild and recovery phases of all causes	Stone Early, and moderate diffuse, hepatocellular damage All patchy lesions Cirrhoses except biliary Passive congestion Early with all causes of complete Severe, late, hematogenous	Carcinoma of ampulla or head of pancreas Fibrosis Stone (intermittent) Severe, diffuse hepatocellular damage Lymphadenopathy at hilus Biliary cirrhosis Terminal cirrhoses Patchy lesions at hilus	Internal blood destruction High gastrointestinal or internal hemorrhage Hemolytic icterus Erythroblastosis fetalis Malaria Pernicious anemia Hemorrhagic infarcts Sickle cell anemia Hemolytic transfusion reaction Hemolytic infection Hemolytic poisons or allergens

Far more valuable in diagnosis than the clinical observations on any one date is the time-intensity curve of the characteristic course of the jaundice and damage to the liver, as illustrated in charts 1 to 8. Note that in each of these figures the position of the curve indicates the type of jaundice to be expected in a typical case at any stage in the course of the disease. The cross hatching indicates the presence of hepatocellular damage detectable by the liver function tests now available. The severity of the impairment of liver function

TABLE 6.—*Causes of Hepatocellular Damage*

Patchy Lesions	Diffuse Lesions
Carcinoma Primary Secondary Cirrhoses Laennec's Biliary (6 types) Congestive Postnecrotic Pigmentary Syphilitic Fatty Wilson's hepatolenticular degeneration Abscesses Amebic Pylephlebitic Cholangitic Pyemic Boeck's sarcoid Hodgkin's disease Lymphosarcoma Leukemias Polycystic liver Amyloidosis Echinococcus cysts	Epidemic hepatitis Homologous serum jaundice Poisons causing hepatic damage Carbon tetrachloride Chloroform Phosphorus Phenylhydrazine Organic arsenicals Cinchophen and neocinchophen Sulfonamide compounds Spirochetal jaundice Hyperthyroidism Eclampsia Ascending hepatitis secondary to cholangitis Severe or prolonged hematogenous jaundice Passive congestion Anoxia Virus pneumonia Infectious mononucleosis Yellow fever

is roughly indicated by the spacing of the cross hatches, far apart if mild and close together if severe. The time scale is in percentage of the total duration of the disease. The typical age of onset is indicated below each figure at the left and the approximate typical duration at the right. Obviously there are wide individual variations from case to case, so each curve should be visualized as having a broad band on either side of it and the cross hatching as showing considerable variation in the spacing and point of starting and ending.

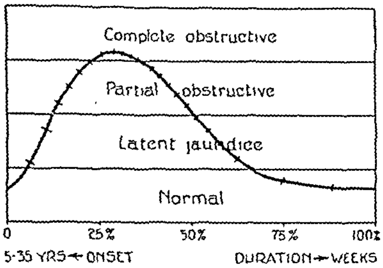

Chart 1.—Infectious hepatitis.

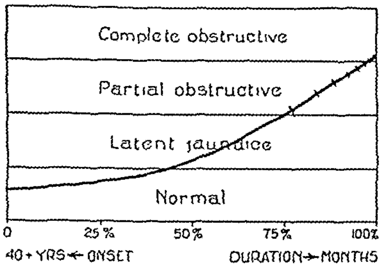

Chart 2.—Metastatic carcinoma.

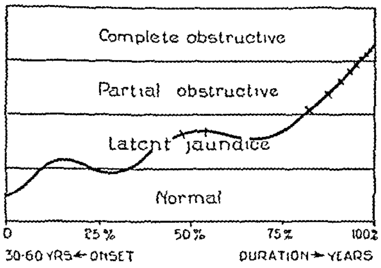

Chart 3.—Laennec's cirrhosis.

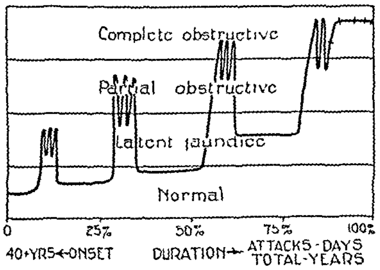

Chart 4.—Cholecystitis with cholelithiasis.

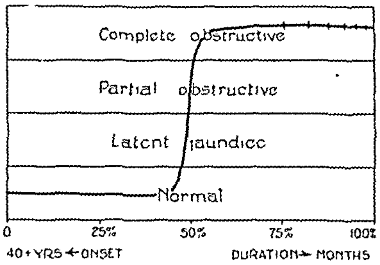

Chart 5.—Carcinoma obstructing common bile duct.

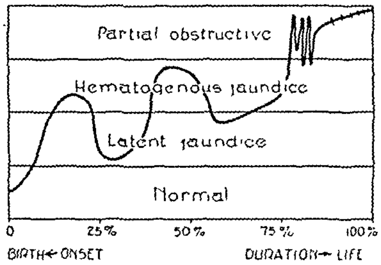

Chart 6.—Hemolytic icterus.

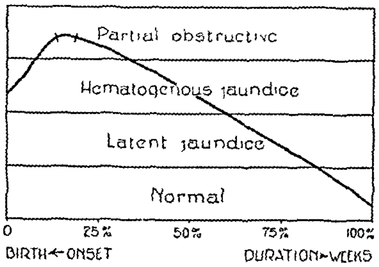

Chart 7.—Erythroblastosis fetalis.

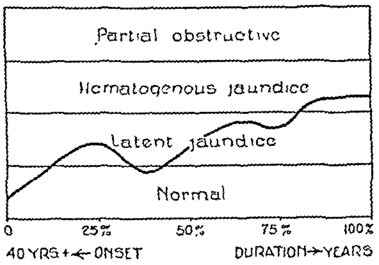

Chart 8.—Pernicious anemia.

Charts 1 to 5 are typical of predominantly obstructive jaundice and charts 6 to 8 of predominantly hematogenous jaundice.

Chart 1 is typical of the diffuse hepatic damage group, and only minor variations from this picture would be found in homologous serum jaundice or hepatic damage due to poisoning or to idiosyncrasy to a drug.

Charts 2 and 3 illustrate characteristic observations in patchy lesions of the liver and charts 4 and 5 of predominantly partial obstructive and predominantly complete obstructive jaundice, respectively. Although identical laboratory observations could be found on some one day in the course of any of the diseases of which these five are prototypes, the character of the curve over a period of time would serve to distinguish them.

Charts 6, 7 and 8 illustrate different forms of hematogenous jaundice. Since latent jaundice is merely subclinical jaundice, in this group of conditions the laboratory tests in the subclinical stage approach those of hematogenous jaundice, whereas in the conditions illustrated by charts 1 to 5 they approach the picture of partial obstructive jaundice.

Occasionally the observations in partial obstructive jaundice, hepatic damage and hematogenous jaundice are of almost equal intensity, as (1) when a patient has two diseases or (2) when extensive internal hemorrhage has occurred from prothrombin deficiency in a patient with a cause for liver damage and obstructive jaundice or (3) when severe hepatic anoxia from anemia and pigment-thickened bile add the obstructive picture to an initially predominantly hematogenous jaundice. Such combinations are the rule in spirochetal disease and yellow fever, are common in severe cases of erythroblastosis fetalis and during the acute crises of hemolytic anemias, and may result from overdosage of drugs, such as phenylhydrazine, that are both hemolytic and hepatoxic.

SUMMARY

Liver function tests alone can never be expected to establish a diagnosis.

They will indicate the presence of disease affecting every liver cell and of patchy disease when more than 80 per cent of the parenchyma is involved.

They will detect subclinical jaundice and classify clinical jaundice as partial or complete obstructive, or hematogenous.

Since hepatocellular damage may occur in the absence of jaundice or in association with any type of jaundice, the term hepatocellular jaundice should be discarded.

An ideal diagnosis as a basis for treatment should indicate specifically the exact anatomic site of each lesion; the nature, stage and extent of the pathologic process; the agent responsible for this specific pathologic process, and the nature and degree of the functional disturbance resulting from the pathologic process. Such a diagnosis can be made only by correlating all the data from the history, physical examination, the tests herein considered and specific tests for the determination of the underlying cause.

DIAGNOSTIC MANAGEMENT OF PATIENTS WITH JAUNDICE

J. E. GIANSIRACUSA, M.D.
and
T. L. ALTHAUSEN, M.D.
San Francisco

In spite of recent advances in our knowledge of hepatobiliary disease, a significant proportion of patients with jaundice still present a baffling problem in differential diagnosis. The importance of this problem is accentuated by the necessity of a decision in a large majority of such cases as to whether surgical intervention is indicated. For this reason we have analyzed 100 recent cases of jaundice which presented problems in differential diagnosis and in which the diagnosis was definitely established by operative intervention, autopsy or clinical course (table 1).

Data from the history, physical examination and laboratory study of these patients which proved of practical diagnostic value will be contrasted with data which are usually considered pertinent but which contributed little to the solution of the problem in our patients. Finally, since a certain number of cases defy all attempts at clinical differentiation, we shall outline a program for the effective handling of patients with jaundice in whom no definite diagnosis as to the type of jaundice can be made, with the object both of avoiding the danger of exploratory operation in the greatest possible number of patients with hepatitis and of guarding the patients from the harmful effects of prolonged extrahepatic obstruction.

The conventional classification of jaundice into hemolytic, obstructive and parenchymatous types according to the original cause of jaundice is followed in this paper. We are cognizant of the fact that mixed types of jaundice, especially obstructive plus parenchymatous are present in most cases after either type of jaundice has existed for several weeks.

In the following analysis the main stress is laid on the differentiation between obstructive and parenchymatous jaundice because patients with hemolytic jaundice seldom present a difficult problem. This is true for two reasons. First, patients with chronic hemolytic icterus as a rule are not very ill and have only mild jaundice, so that surgical intervention in the right upper quadrant of the abdomen is seldom considered. Second, the presence of several characteristic clinical features usually enables the clinician to distinguish hemolytic from other types of jaundice. These features are a familial history, repeated painless attacks of jaundice with an icterus index under 50 units, normal stools, absence of bilirubin in the urine and reticulocytosis.

RESULTS

I A. *Data of Value in the History*—Sex: In our series data of value in the history (table 2) revealed that obstructive jaundice was twice as common in men as in women. This was due to the fact that men with carcinoma of the pancreas obstructing the common biliary duct comprised 91 per cent of all such cases. The sex of our patients was of some assistance also in the diagnosis of hepatic cirrhosis, since 66 per cent of cases of this disease were encountered in men and 34 per cent in women, giving a ratio of 2 to 1. Studies in the literature[1] reveal an almost 4 to 1 preponderance of obstructive jaundice in men.

Past History of Cholecystic Disease: There was a past history of cholecystic disease in 85 per cent of our patients with choledocholithiasis and in 30 per cent of patients with jaundice due to other causes. Our data in this respect are in general agreement with those found in the literature.

Biliary Colic: Seventy-five per cent of our patients with typical biliary colic had obstructive jaundice and 25 per cent had parenchymatous jaundice. However, only 40 per cent of our patients with stone in the common bile duct had biliary colic. Lichtman[2] and Kiefer[3] described colicky pain in the right hypochondrium in a considerable number of patients with obstruction due to carcinoma of the pancreas or biliary ducts, while Weiss[4] stated that hepatitis may be ushered in by severe epigastric pain radiating to the right shoulder. Biliary colic, then, may be present in all types of jaundice but is seen most frequently in choledocholithiasis. A positive history is of more diagnostic significance than a negative one.

Chills and Fever: Chills and fever are common symptoms accompanying jaundice and are usually considered of little diagnostic value, since they may usher in an attack of hepatitis or may be associated with cholangitis in obstructive jaundice.[2] However, we found them of some significance, since 70 per cent of our patients with chills and fever had obstructive jaundice and 50 per cent had a stone in the common bile duct.

Alcoholism: Eighty-eight per cent of patients who admitted moderately severe to severe alcoholism had parenchymatous jaundice. Such an alcoholic history was present in 64 per cent of our patients suffering from hepatic cirrhosis with jaundice. Recent studies of cirrhosis of the liver without reference to jaundice revealed an incidence of alcoholism of between 38 per cent [1a] and 87 per cent.[1b]

Loss of Weight: Most types of jaundice are frequently accompanied by loss of weight. In cirrhosis of the liver [1b] and in choledocholithiasis [5] the loss of weight is usually slow and associated with digestive disturbances, whereas in carcinoma of the pancreas it often is not only well defined but also rapidly progressive.[6] Among patients in this series who lost 10 Kg. or more in weight, 88 per cent had obstructive jaundice, and in 66 per cent this loss of weight was due to carcinoma of the pancreas. In 11 per cent of cases the severe loss of weight was associated with hepatitis. Twelve patients reported not only a pronounced but also a rapidly progressive loss in weight, and all of them were found to have carcinoma of the pancreas. A positive history is again more significant than a negative one, since only 55 per cent of our patients with pancreatic carcinoma had a weight loss exceeding 10 Kg.

* Figures in parentheses indicate the percentage of patients with a given diagnosis in whom this observation was made.

I B. *Data of Little Value in the History.*—Age: The incidence of age usually plays a prominent part in statistical studies of hepatic disease. For example, in Flood's series,[5] 80 per cent of patients with obstructive jaundice were over 40 years of age and 80 per cent of patients with parenchymatous jaundice were under 40 years of age. The average age of our patients with obstructive jaundice was 57 years and that of our patients with parenchymatous jaundice, 46 years, thus allowing no useful diagnostic conclusions in individual cases. Our 2 patients with acute yellow atrophy of the liver were 62 and 79 years of age.

Prodromal Symptoms: Anorexia, nausea, epigastric distress, malaise and symptoms referable to the upper part of the respiratory tract are frequently described as the preicteric stage of acute hepatitis.[7] In our series such prodromal symptoms were of minor importance in differential diagnosis, since they were present not only in patients with acute hepatitis but also in 2 of 5 patients with obstructive jaundice.

Pain in the Abdomen and Back: Exclusive of biliary colic, pain in the abdomen and back occurred in nearly one third of our patients, of whom 58 per cent had obstructive jaundice and 42 per cent had parenchymatous jaundice. The type or exact location of pain experienced by these patients was of no greater value in differential diagnosis than the incidence of pain. This was not unexpected, since both inflammatory and obstructive lesions of the hepatobiliary system are capable of causing distention of Glisson's capsule or of the biliary apparatus and in this manner causing pain.

Relationship of Onset of Jaundice to Onset of Pain: Weiss [4] stated that jaundice appears within a matter of hours after the impaction of a gallstone in the common duct, whereas it takes several days for jaundice to be established after the onset of hepatitis. Berk [6] found that in 15 of 18 patients with carcinoma of the pancreas, in whom the order of appearance of these two symptoms could be established, pain occurred before jaundice. We were able to ascertain the order of appearance of these two symptoms in 26 of our 60 patients with pain but were unable to draw any useful diagnostic conclusions. Among 18 patients with biliary obstruction and pain, the pain preceded the jaundice in 6 cases and coincided with it in 12. Among 8 patients with hepatitis and pain, the pain preceded the jaundice in 3 instances, coincided with it in 3 and followed it in 2.

Absence of pain as a characteristic of obstructive jaundice due to malignant tumors versus the presence of pain as a characteristic of obstructive jaundice due to choledocholithiasis was at one time emphasized more than it has been since the publication of several papers dealing with this subject.[8] In our series the jaundice was painless in 43 per cent of patients with carcinoma of the pancreas, in 42 per cent of patients with hepatitis and in 40 per cent of patients with stone in the common bile duct. Obviously the absence of pain offers no help in the differential diagnosis of jaundice.

Pruritus: Itching is a common symptom of jaundice which is often considered to favor the diagnosis of biliary obstruction.[9] In this study pruritus was of no diagnostic significance, since patients complaining of it had parenchymatous jaundice in 53 per cent of cases and obstructive jaundice in 47 per cent of cases. In Lichtman's experience [2] itching was also independent of the type and severity of jaundice.

II A. *Physical Observations of Value.*—Hepatomegaly: Among the physical observations of value (table 3), palpable enlargement of the liver was present in 59 per cent of our patients and was found with equal frequency in cases of obstructive and of parenchymatous jaundice. Decided hepatomegaly with the edge of the liver 7 cm. or more below the costal margin was present three times more frequently in jaundice associated with parenchymatous disease than in obstructive jaundice. Among patients with obstructive jaundice

and enlargement of the liver a large majority (73 per cent) of cases were due to carcinoma of the pancreas. It appears that the rapidly progressive and complete obstruction which results from this cause is more likely to produce enlargement of the liver than is the incomplete and often intermittent obstruction due to choledocholithiasis. Data in the literature on the size of the liver in various diseases which lead to jaundice vary considerably.[10] The hazards of attaching too much significance to hepatic enlargement have been shown by Rives, Romano and Sandifer,[8a] who were able to confirm at autopsy the clinical finding of hepatomegaly in less than one half of their cases. One of us (T. L. A.) had a patient in whom the lower edge of the liver, which was subsequently proved to be normal, was pushed down to the level of the umbilicus by advanced pulmonary emphysema.

Ascites: Free fluid in the abdomen is an observation of great diagnostic value. Ninety-one per cent of our patients with ascites had parenchymatous jaundice, and in 76 per cent of cases it was due to cirrhosis of the liver. Sixty nine per cent of our patients with hepatic cirrhosis and jaundice had clinically demonstrable ascites. Studies by other clinicians are in agreement with these observations.[11]

Collateral Subcutaneous Venous Circulation: Ninety-one per cent of patients with collateral subcutaneous venous circulation had parenchymatous jaundice. In 82 per cent of cases it was due to cirrhosis of the liver. However, only 38 per cent of patients with cirrhosis and jaundice and only 47 per cent of patients with cirrhosis, jaundice and ascites showed evidence of collateral circulation. In the literature collateral circulation is reported in from 23 per cent to 76 per cent of patients with hepatic cirrhosis.[11b] The conclusion appears justified that the presence of collateral circulation strongly points to the existence of parenchymatous jaundice, which in most cases will be due to cirrhosis of the liver.

Angiomas: Angiomas of the acquired arterial spider type were found in this series only in patients with parenchymatous jaundice due, with 1 exception, to cirrhosis of the liver. However, Bean [12] in a series of 232 patients with hepatic disease also found such angiomas in 2 instances of obstructive jaundice. Eighty per cent of his patients with angiomas were suffering from cirrhosis of the liver. The observation of acquired spider angiomas, then, is good evidence of parenchymatous jaundice, which in a large majority of cases is due to hepatic cirrhosis.

Palpable Gallbladder: In 89 per cent of our patients with a palpable gallbladder the jaundice was due to carcinoma of the pancreas and in 11 per cent to choledocholithiasis. On the other hand, only 35 per cent of our patients with carcinoma of the pancreas had a clinically enlarged gallbladder. These figures are generally in accord with those in the literature.[13] Flood [5] also occasionally found a palpable gallbladder in patients with catarrhal jaundice. Therefore, notwithstanding some exceptions, Courvoisier's law is still valid when a palpable gallbladder is present.

Splenomegaly: A palpably enlarged spleen was associated in this series with parenchymatous jaundice in 60 per cent of cases, with hemolytic jaundice in 14 per cent and with obstructive jaundice in 26 per cent. Therefore, 3 of 4 patients with splenomegaly had nonsurgical types of jaundice. According to published data splenomegaly is mainly present in cirrhosis of the liver and in acute hepatitis but occasionally also in choledocholithiasis with cholangitis and in carcinoma of the pancreas.

II B. *Physical Observations of Little Value.*—Bradycardia: Slowing of the pulse rate figures prominently in most textbook discussions on jaundice. Most authors find it predominantly in catarrhal jaundice.[14] On the other hand, MacKenzie [15] stated that he never met with bradycardia in jaundice. We observed a significant slowing of the pulse rate in only 2 patients in this series and therefore cannot consider it of any diagnostic help.

Fever: Low grade, chronic fever was present in 39 per cent of cases in this series. It was observed with approximately equal frequency in cases of obstructive and of parenchymatous jaundice. Other authors reported approximately the same incidence of low grade fever in patients with jaundice.[16] One of these reports has stated that patients with carcinoma of the pancreas seldom have any fever.

Negative	(11)	..	(94)	..

* Figures in parentheses indicate the percentage of patients with a given diagnosis in whom this observation was made.

Hepatic Tenderness: A tender liver was found in only 13 per cent of our patients but was of some diagnostic significance when present, since in fully 10 per cent of the cases it was due to parenchymatous disease of the liver. Reports in the literature [17] indicate a higher incidence of hepatic tenderness in jaundice than we found and state that it occurs most frequently in acute hepatitis, less frequently in choledocholithiasis, and seldom in cirrhosis of the liver or in carcinoma of the pancreas.

III A. *Laboratory Tests of Value.*—Gastrointestinal Series: An analysis of the value of laboratory tests (table 4) showed that roentgenologic studies of the gastrointestinal tract can be useful in the differential diagnosis of jaundice in the following manner: (1) by suggesting the presence of a pancreatic carcinoma when widening of the duodenal loop, partial obstruction of the third part of the duodenum or deformity of the pylorus or duodenum due to infiltration by tumor are present; (2) by indicating the probability of hepatic cirrhosis when varices are found in the esophagus, and (3) by calling attention to the possibility of metastatic involvement of the extrahepatic or intrahepatic biliary ducts when a primary tumor of the gastrointestinal tract, usually of the stomach, is discovered.

[17] Ratnoff and Patek.[1c] Weiss.[4] Flood, Seegal, Spock and Loeb.[5]

In our series characteristic changes in the duodenum were found in 45 per cent of patients with cancer of the pancreas. Esophageal varices were detected in 36 per cent of patients with cirrhosis of the liver and jaundice. Berk[6] reported positive roentgenologic observations in 37 per cent of 367 collected cases of pancreatic carcinoma.

Serum Proteins: A serum albumin of 3.5 Gm. per hundred cubic centimeters or less occurred with equal frequency in patients with obstructive and with parenchymatous jaundice. On the other hand, 75 per cent of patients who had a low serum albumin level with a high serum globulin determination were suffering from parenchymatous jaundice, usually due to cirrhosis of the liver. The importance of hyperglobulinemia in addition to the hypoalbuminemia for the differential diagnosis of jaundice has not been stressed by writers on this subject.[18]

Intravenous Galactose Test: The value of galactose in the differential diagnosis of jaundice lies in the observation that, unlike most other functions of the liver, the ability to metabolize galactose is impaired relatively little by obstructive jaundice of even several months' duration. In a previous paper[19] one of us (T. L. A.) called attention to the unreliable results with the conventional oral galactose test, which is influenced not only by the ability of the liver to metabolize galactose but by the rates of intestinal absorption and renal excretion of this sugar. At the same time there was described a method of administering galactose intravenously and of measuring the unused portion of galactose in the venous blood at the end of the test, which rendered the galactose test more useful for the differentiation of obstructive from parenchymatous jaundice. In this paper, 82 per cent of 33 unselected patients with obstructive jaundice of less than six months' duration had less than 20 mg. of galactose per hundred cubic centimeters in the blood seventy-five minutes after the intravenous injection of 1 cc. of a 50 per cent solution of galatose per kilogram of body weight, while 81 per cent of 26 unselected patients with parenchymatous jaundice had more than this amount of galactose in the blood.

In the present series all patients with uncomplicated obstructive jaundice due to stone in the common bile duct had less than 20 mg. of galactose per hundred cubic centimeters in the blood at the end of the test. Six patients with choledocholithiasis and superimposed biliary cirrhosis had higher values for galactose. All the latter patients had a long history of repeated attacks of biliary colic associated with jaundice, chills and fever; hence, it was easy to distinguish this group clinically from patients with uncomplicated obstructive jaundice. In all these patients the clinical diagnosis of biliary cirrhosis was confirmed by operative procedures and in half of them it was also confirmed by biopsy of the liver.

In all but 1 patient with uncomplicated obstructive jaundice due to carcinoma of the pancreas the blood galactose level was under 20 mg. per hundred cubic centimeters. In the 1 exception the borderline figure of 25 mg. per hundred cubic centimeters was obtained. Three patients with carcinoma of the pancreas had higher values for galactose. Two of them also had cirrhosis of the liver, as shown by operation and biopsy, and the third patient had massive metastatic growths in the liver. Two patients with jaundice due to benign postoperative stricture of the common duct had a normal galactose tolerance.

In summary, practically all (97 per cent) patients with uncomplicated obstructive jaundice were identified correctly by the intravenous galactose test. If we are to include in the group of obstructive jaundice the cases complicated by hepatic cirrhosis and the case with massive metastases to the liver, we still get a correct answer in 78 per cent of the cases. The mean galactose blood level of all patients with obstructive jaundice was 15 mg. per hundred cubic centimeters.

Seventy-nine per cent of patients with cirrhosis of the liver had more than 20 mg. of galactose per hundred cubic centimeters in the blood. All these patients had an icterus index over 50 units. Twenty-one per cent of patients with cirrhosis of the liver had a galactose level of less than 20 mg. per hundred cubic centimeters in the blood, and all of them had an icterus index under 50 units. In addition to the mild degree of icterus, which usually robs the case of urgency because surgical intervention is not contemplated, in most of the latter cases the presence of other signs which pointed to parenchymatous hepatic disease, such as ascites, spider angiomas and cutaneous collateral circulation, made the diagnosis clear.

Seventy-three per cent of patients with acute hepatitis had a galactose blood level in excess of 20 mg. per hundred cubic centimeters. Twenty-seven per cent had less than 20 mg. of galactose per hundred cubic centimeters in the blood. In the latter group, in all but 1 case the hepatitis was mild (with an icterus index under 50 units) or of short duration and was undergoing rapid improvement when the test was performed.

Two patients with acute yellow atrophy of the liver had a striking inability to metabolize galactose. Their blood galactose levels were 129 and 145 mg. per hundred cubic centimeters. The highest figure for galactose in the blood which we observed in acute hepatitis with recovery was 116 mg., and the highest figure obtained in cirrhosis of the liver was 92 mg., per hundred cubic centimeters. This limited experience suggests that galactose levels over 125 mg. per hundred cubic centimeters are of grave prognostic significance. This information is of all the more value, since the 2 instances of extremely high values for galactose were obtained by us before other indications of the gravity of the situation appeared and while the patients had few subjective complaints. In 1 of these cases the outcome of the test was instrumental in bringing a close relative from a distant part of the country to the patient's bedside before death occurred.

In summary, 77 per cent of all patients with parenchymatous jaundice were identified correctly by means of the intravenous galactose test. Were we to exclude from our material patients with mild jaundice (with an icterus index under 50 units) or with jaundice lasting less than a week, the accuracy of the test in parenchymatous jaundice would rise to 98 per cent.

[19] Bassett, A. M.; Althausen, T. L., and Coltrin, G. C.: A New Galactose Test for the Differentiation of Obstructive from Parenchymatous Jaundice, Am. J. Digest. Dis. 8: 432 (Nov.) 1941.

The mean galactose level of the blood was 56 mg. per hundred cubic centimeters. King and Aitken[20] as well as Maclagan[21] obtained comparable results with the intravenous galactose test. Combining the results of the intravenous galactose test in all cases of jaundice, it is seen that the outcome of the test alone made the differentiation between obstructive and parenchymatous jaundice in our series in 3 of 4 cases. When certain simple additional clinical data are taken into consideration, it becomes possible to determine correctly the type of jaundice in almost all cases

Prothrombin Response to Vitamin K: Maintenance of a normal prothrombin level in the plasma is one of the functions of the liver. This function can be fulfilled only in the presence of an adequate supply of vitamin K from the intestine. Obstructive jaundice lowers the prothrombin level by interfering with the intestinal absorption of vitamin K and by creating a vitamin K deficiency. Such a deficiency hypoprothrombinemia is corrected rapidly (often in six hours) by the parenteral administration of vitamin K. Parenchymatous jaundice produces hypoprothrombinemia by interfering with the ability of the liver to form prothrombin. Consequently in the latter the administration of vitamin K either does not raise the prothrombin level at all or does so only slowly. This difference, as has been repeatedly pointed out,[22] can be used for the differential diagnosis between obstructive and parenchymatous jaundice.

In the present study the prothrombin level was determined by the method of Quick[23] The patient was then given an injection of the contents of one ampule of a vitamin K preparation, menadione sodium bisulfite ("hykinone" Abbott), and the prothrombin level was determined again twenty-four to forty-eight hours later. Elevation of the prothrombin level was considered significant only if the original level was 70 per cent or less and the increase 20 per cent or more.

Among our patients with obstructive jaundice 89 per cent responded with a significant increase of an initially low prothrombin concentration. Among those who failed to respond superimposed biliary cirrhosis accounted for one half of the cases. Allen[24] also found that the presence of cholangitis with fever impaired the prothrombin response In the group of our patients with parenchymatous jaundice 94 per cent showed no increase in the prothrombin level. These figures indicate a satisfactory accuracy on the part of the prothrombin response to vitamin K in the differentiation of the obstructive from the parenchymatous type of jaundice. There was also excellent correlation between the results of the intravenous galactose test and the response of prothrombin to vitamin K.

III B. *Laboratory Tests of Little Value.*—Cholecystography: Cholecystography was of limited value in differentiating between cases of obstructive and of parenchymatous jaundice in this series. It can be said that normal visualization of the gallbladder tends to rule out cholecystic disease. However, since the gallbladder was not visualized in 77 per cent of our cases of jaundice due to cholecystic disease, acute hepatitis, hepatic cirrhosis and benign or malignant obstruction of the common duct, this procedure was of little value in differential diagnosis.

Intravenous Hippuric Acid Test: The test based on the ability of the liver to provide aminoacetic acid for the formation of hippuric acid from sodium benzoate has proved itself a sensitive general liver function test. In the series here reported excretion of sodium benzoate was impaired in 82 per cent of patients with obstructive jaundice, regardless of the duration of jaundice and in 90 per cent of patients with parenchymatous jaundice. These figures correspond to our previously reported observations[19] and to the experience of other workers.[25] They indicate that the test is so sensitive that it records the relatively slight hepatic injury caused by regurgitation of bile in obstructive jaundice on a par with the more serious injury incident to various forms of hepatitis. For this reason it is not suitable for differentiation of these two types of jaundice.

Other Liver Function Tests: Several other tests, including the qaulitative van den Bergh, total cholesterol, cephalin flocculation, alkaline phosphatase and roughly quantitative urobilinogen determinations by the method of Wallace and Diamond,[26] were performed in a portion of the cases included in this series. Except in isolated instances we found them of no great value in differentiation between cases of obstructive and of parenchymatous jaundice. This was also the reported experience of other investigators.[27]

EXPECTANT MANAGEMENT OF JAUNDICE

In any sufficiently large series of patients with jaundice in spite of the best efforts of the clinician there is likely to remain a small residual number of cases in which the most meticulous history, careful physical examination and extensive laboratory investigation fail to produce a satisfactory identification of the type of jaundice present. In such cases the attending physician can substitute intelligent management for a definite diagnosis. Such management consists of supportive and symptomatic treatment for a period of two months from the onset of jaundice and serial determinations of bilirubinemia by means of the icterus index or the quantitative van den Bergh test at intervals of two weeks. If at the end of this period there is no consistent diminution in the intensity of jaundice, exploratory operation should be advised.

It has been shown that most cases of acute hepatitis begin to clear up before the end of two months. Most patients with subacute or acute atrophy of the liver will also either show definite improvement or die during this period. This leaves practically only patients with obstructive jaundice who can be either cured by removal of a benign obstruction from the common bile duct or relieved by a palliative anastomosis of the gallbladder to the duodenum or stomach if the obstruction is due to a malignant tumor.

The objection to an exploratory operation before the end of two months is the high operative mortality of patients with hepatitis, especially when hypoprothrombinemia is present. On the other hand, expectant treatment for two months in the presence of obstructive jaundice, especially when supportive treatment is used, causes relatively little harm, since even complete obstruction of the common duct is tolerated fairly well for several months,[28] while obstruction permitting the leakage of 15 to 20 per cent of the normal amount of bile into the intestine is compatible with fair health indefinitely.[29] It is also useful to recall here, as pointed out by Watson,[30] that obstruction of the common bile duct due to gallstones is practically never complete. Complete obstruction of the common bile duct is usually caused by carcinoma of the head of the pancreas or of the bile ducts, and the prognosis is definitely poor in any case. Even with these precautions, on infrequent occasions a patient with prolonged hepatitis may be subjected to exploratory laparotomy. However, this risk must be accepted in order to avoid the development of biliary cirrhosis in case of further delay in a far greater number of patients with obstructive jaundice, especially when the obstruction is of a benign nature.

At present with the aid of the intravenous galactose test and the prothrombin response to vitamin K we find it necessary only in rare instances to resort to the expectant management of patients with jaundice. However, before the advent of these two tests one of us (T. L. A.) had considerable experience with such management, and the results were gratifying.

SUPPORTIVE AND SYMPTOMATIC TREATMENT OF JAUNDICE

1. The diet should be high in protein (125 Gm.) and carbohydrate (360 Gm.) and low in fat (60 Gm.). Alcohol must be excluded totally and meat limited to one meal a day. If the patient is unable to eat sufficient food at meal time, interval feedings should be instituted. Intravenous infusions of dextrose and amino acids are useful only when for some reason, such as vomiting, the patient is unable to take sufficient nourishment orally.
2. A generous supplement of vitamins A and B complex, ascorbic acid, vitamins D and K should be prescribed.
3. Hypochromic anemia, if present, should be treated with preparations of iron. For hyperchromic macrocytic anemia, liver extract or folic acid should be administered.
4. Calcium is prescribed to help prevent osteoporosis.
5. For itching, 0.5 mg. of ergotamine tartrate can be injected subcutaneously once a day for several days. Advanced age and weak or absent pulsations of the arteries of the foot are contraindications to this drug.
6. Insulin should be given only for coexisting diabetes mellitus.
7. Salts of bile acids are of questionable value.

COMMENT

The chief data in the history, physical examination and laboratory study which are of diagnostic value in jaundice have been discussed. The data of little differential value have also been mentioned.

In many patients with jaundice the correct diagnosis can be made from the history and physical examination alone. For example, a middle-aged patient in whom, after a prolonged period of malaise and nausea, there develops jaundice with decided pain in the right upper quadrant referred to the back, pruritus and low grade fever may be suffering from either obstructive or parenchymatous jaundice. In such cases, an additional history of alcoholism would point to cirrhosis of the liver or hepatitis; male sex with definite progressive loss of weight would strongly suggest carcinoma of the pancreas; a history of cholecystic disease, of biliary colic or of chills and fever would favor a diagnosis of stone in the common bile duct. A physical examination may reveal a palpable gallbladder, which would suggest carcinoma of the pancreas, or disclose one or more of the following signs: extremely large liver, ascites, collateral subcutaneous circulation, spider angiomas or splenomegaly, which would point to parenchymatous jaundice and probably cirrhosis of the liver. However, in many instances the history and physical examination do not yield information of a decisive nature. The laboratory study may then answer the crucial question whether the jaundice is due to extrahepatic block and surgical intervention is necessary or whether it is due to parenchymatous disease of the liver and medical treatment alone is indicated. The gastrointestinal series of tests may furnish presumptive evidence of carcinoma of the pancreas or of hepatic cirrhosis. A low serum albumin level with a high serum globulin determination favors parenchymatous jaundice. However, in our experience final recourse is usually to liver function tests. Here it must be remembered that liver function tests involving the ability of the liver to excrete certain substances, such as dyes or bilirubin, are useless in patients with jaundice. It is also well to bear in mind that the most sensitive liver function tests are not always the best for a given purpose. For example, the high sensitivity of the hippuric acid test makes it useless for the differential diagnosis of jaundice. The most decisive factor in differentiation between obstructive and parenchymatous jaundice is the ability of the liver to metabolize galactose and to produce prothrombin following an injection of vitamin K. If these functions of the liver are not impaired, or are impaired only slightly, the case is in the domain of the surgeon. If they are greatly impaired the case is almost always strictly a medical problem. If the results are inconclusive or conflicting, supportive treatment and serial determinations of bilirubinemia are indicated for a period of two months from the onset of jaundice. During this period the large majority of patients with parenchymatous disease of the liver are either on the way to recovery or have died from acute yellow atrophy of the liver. Those remaining unimproved, with few exceptions, have obstructive jaundice and should be subjected to exploratory laparotomy.

SUMMARY

1. One hundred cases of jaundice which presented diagnostic problems and in which the diagnosis was confirmed by operation, autopsy or clinical course are analyzed.
2. The relative value of data obtained from the clinical history, physical examination and laboratory study in the differentiation between obstructive and parenchymatous jaundice is pointed out.
3. The usefulness of the intravenous galactose test is demonstrated by the fact that, when taken alone, it

made the differentiation between obstructive and parenchymatous jaundice in 3 out of 4 cases. When taken in conjunction with certain simple additional clinical data, this test made it possible to identify the type of jaundice in almost all cases.

4. The diagnostic accuracy of the prothrombin response to vitamin K is shown by the fact that it was present in 9 of 10 patients with obstructive jaundice and was absent in the same proportion of patients with parenchymatous jaundice.

5. A program is outlined for the effective handling of the small number of patients with jaundice in whom no definite diagnosis as to the type of jaundice can be made in spite of all efforts.

THE DIAGNOSIS OF INFECTIOUS HEPATITIS

RICHARD B. CAPPS, M.D.
Chicago
CAPTAIN VICTOR M. SBOROV
Medical Corps, Army of the United States
and
M. HERBERT BARKER, M.D.
Chicago

Interest in infectious hepatitis has been greatly increased by the large number of cases occurring in our armed forces during the war. Whether there has been a corresponding rise in incidence among civilians in the United States is not known since it is not generally reportable; but it is worthy of note that a significant rise in the civilian rate has been reported in several other countries.[1] We have already pointed out that this disease is more serious than was previously thought and have emphasized the importance of its prompt recognition and proper treatment.[2] However, the diagnosis of sporadic cases, especially the nonicteric types, offers difficulties not encountered during epidemics. Because of these difficulties we feel justified in presenting a detailed report of the practical problems involved in the clinical diagnosis.

MATERIAL AND METHODS

Our experience, gained largely in the army, is based on the observation of approximately 8,000 cases of infectious hepatitis, of which 2,000 were systematically studied. These include postvaccinal hepatitis seen in 1942, epidemic hepatitis in the Mediterranean theater,[2a, b] a recent series of varied types studied in this country in an army general hospital and cases seen in civilian practice since the war. Almost all the available methods for the study of hepatic function have been extensively employed. The procedures referred to in this paper are as follows. Bilirubinuria has been determined by the methylene blue test[2a] and by Hawkinson, Watson and Turner's so-called strip test.[3] The serum bilirubin has been measured by the acetone icterus index[4] or by Ducci and Watson's modification of the van den Bergh test.[5] Watson, Schwartz, Sborov and Bertie's new quantitative method has been used for urobilinogen.[6] Cholesterol esters have been determined by the Sperry and Schoenheimer technic.[7] Standard methods have been employed for other tests.[2a, b].

GENERAL CONSIDERATIONS

At the outset it must be recognized that there is no specific test for this disease. So far it has proved impossible to develop an immunologic or bacteriologic method for specific identification. Acute hepatic injury may be caused not only by the virus of infectious hepatitis but also by other infectious agents, notably virus pneumonia, infectious mononucleosis, acute brucellosis, amebiasis and malaria, as well as by certain hepatotoxins such as carbon tetrachloride, arsenic, phosphorus, cinchopen and probably the sulfonamide drugs.[8] However, in the absence of other satisfactory etiologic explanation and in the presence of a compatible clinical picture it appears safe to assume that acute hepatitis is almost always due to the virus of infectious hepatitis or a closely allied strain.

The clinical course of this disease is characterized by an acute febrile nonicteric prodromal period lasting about seven days followed by an acute icteric stage of about three weeks' duration. Frequently, clinical jaundice fails to develop after the febrile prodromes, and this is referred to as acute hepatitis without jaundice.[2a] Finally, about 10 per cent of acute cases progress to so-called chronic hepatitis.[2b] Since the diagnostic problems, as well as the diagnostic criteria and methods, are different in each of these stages or types, it is necessary to discuss them separately.

Of general diagnostic value is a history of other cases of the disease in the family or neighborhood or a history of exposure to blood or blood products parenterally. In this regard transfusions, plasma, convalescent serum[9] or any type of hypodermic injection[10] in the previous four months is a possible source

of infection. At the same time it is desirable to rule out exposure to such common substances as carbon tetrachloride, chloroform, arsenic and various commercial solvents. Although such exposure may constitute the sole cause of an acute hepatitis it may also act as a secondary aggravating factor in what is primarily an infectious hepatitis.

TABLE 1.—*Diagnostic Significance of Observations in the Prodromal or Preicteric Stage of Infectious Hepatitis*

Presumptive Observations	Suggestive Observations
1. Liver large and tender	1. Liver tender but not enlarged
2. Hyperbilirubinemia	2. Splenomegaly
3. Bilirubinuria	3. Low cervical adenopathy
	4. Leukopenia with atypical lymphocytes
	5. Other liver function tests moderately to strongly positive

PRODROMAL STAGE

The diagnosis of infectious hepatitis in the prodromal stage is infrequently more than presumptive. The symptomatology cannot be clearly distinguished from that of other acute febrile illnesses. Furthermore, the presence of fever introduces the possibility of transitory secondary hepatic changes which diminish the significance of liver function tests. The characteristic feature of infectious hepatitis is that the distinctive physical and laboratory observations persist for some days after the abatement of fever and usually become more pronounced.

The diagnosis should be suspected when anorexia and nausea with or without vomiting are prominent and persistent. Moderately severe headache, a few loose stools with excessive flatus, and distress in the right upper quadrant of the abdomen are also common and important symptoms. Although fever as high as 104 F. may be present for several days, shaking chills are seldom seen. In the homologous serum type of hepatitis and in about 10 per cent of cases of the epidemic hepatitis type there is an insidious and relatively afebrile onset.

The more important physical and laboratory diagnostic observations are listed in table 1. We do not believe that a presumptive diagnosis should be made at the prodromal stage without at least one of the criteria in that column being present. Unfortunately, all three are often absent. It is to be noted that the appearance of bilirubin in the urine is not only an early observation but may occur without abnormality in the serum bilirubin or in the presence of such a small rise in the prompt direct type of serum bilirubin that the icterus index is not significantly altered.[11]

If other liver function tests are rather strongly positive this fact is decidedly suggestive of primary hepatitis. The flocculation and the quantitative urine urobilinogen tests are the most helpful and practical in this respect. Moderate elevation of the latter, however, must be discounted in the presence of fever. It is ordinarily not practical to use the sulfobromophthalein sodium test at this point, although a moderate degree of dye retention is significant.

The diagnosis is seldom established until after the initial febrile period has passed and either frank jaundice appears or positive observations persist.

ACUTE STAGE

The diagnosis of infectious hepatitis in the acute icteric stage is relatively easy and is adequately discussed in all standard texts. Acute hepatitis without jaundice is, however, a relatively new concept.[2a] The diagnosis is based on the persistence of the prodromal observations after the subsidence of fever. Symptoms of decided lassitude, anorexia, mild looseness of the stools, intestinal cramps, headache and aching in the right upper quadrant of the abdomen and right lumbar region are present.

In the absence of fever, results of liver function tests have increased significance. As shown in table 2, bilirubinemia, bilirubinuria or moderate sulfobromophthalein sodium retention are diagnostic if present. However, the first two are often so transitory that they are missed. A positive flocculation test or quantitative urobilinogen determination associated with characteristic clinical observations are also adequate for diagnosis.

An important point in the history is the characteristic aggravation of symptoms, especially the pain in the right upper quadrant of the abdomen, after physical exertion or jolting activities such as rough automobile rides. Patients that have been exercising and do not have an enlarged tender liver do not have acute hepatitis. On the other hand, the physical examination of patients with acute infectious hepatitis who have been at rest in bed often reveals a normal liver.

CHRONIC HEPATITIS

Chronic hepatitis is a condition which develops in certain instances following acute hepatitis either with or without jaundice.[2b] For prognostic and therapeutic reasons it is of value to distinguish two types, even though they probably represent different phases of the same disease.[12] Chronic active hepatitis is characterized by recurrent bouts of extreme lassitude, easy fatigue, looseness of the stools, intestinal cramps, increased flatus, anorexia, headaches and pain in the right upper quadrant and the right lumbar region. Jaundice may occur. The liver is enlarged and tender. Symptoms and observations are all aggravated by

TABLE 2.—*Diagnostic Significance of Observations in Acute Hepatitis Without Jaundice After the Acute Febrile Prodomes Have Subsided*

The Persistence of Observations Associated with Suitable Symptoms Is Most Significant

Diagnostic Observations	Confirmatory Observations
1. Large tender liver	1. Same physical observations as in prodromal stage
2. Hyperbilirubinemia	2. Leukopenia with atypical lymphocytes
3. Bilirubinuria	3. Other liver function tests only slightly positive
4. Positive sulfobromophthalein sodium excretion test	
5. Other liver function tests at least moderately positive

physical exertion or jolting. Inactive hepatitis, on the other hand, is associated with relatively few symptoms and is not aggravated by exercise. Fat intolerance, flatus and moderate ease of fatigability may be present. The liver may be enlarged, but it is not tender. Objective evidence of hepatic dysfunction is obtained from laboratory procedures. Low grade bilirubinemia of the indirect type may be found.

TABLE 3.—*Diagnostic Observations in Chronic Infectious Hepatitis*

A history of acute infectious hepatitis preferably with jaundice is, of course, essential. In the active form this should be followed by residual or recurrent symptoms, whereas in the inactive form symptoms are minimal or absent

Chronic Active Hepatitis	Chronic Inactive Hepatitis
1 Tender enlarged liver	1. Normal or enlarged nontender liver
2. Aggravation of symptoms and observations with exercise	2 No relation of observations to exercise
3 Bilirubinemia of prompt direct type	3 Bilirubinemia if present is indirect type
4 Sulfobromophthalein sodium retention or other positive liver function tests only if first two observations in this column are positive	4. Sulfobromophthalein retention or other positive liver function tests static

The diagnostic observations in both the active and inactive forms of chronic infectious hepatitis are shown in table 3. A history of acute hepatitis with jaundice at the onset of the present illness should be obtained. Although the chronic disease not infrequently develops after an acute attack of the nonicteric type, caution must be used in such cases in making a diagnosis since the causation is difficult to establish; a typical febrile relapse with jaundice is probably the most diagnostic observation.[2b]

In the active form of chronic hepatitis the liver should always be tender and enlarged, although exercise may be necessary to make these factors manifest. The exercise tolerance test developed by one of the authors (R. B. C.) is often of the greatest diagnostic value.[13]

Laboratory evidence of hepatic dysfunction does not distinguish between the active and inactive types of the disease, except that strongly positive tests are usually but not necessarily associated with the former. An elevation of the prompt direct type of bilirubinemia is probably the only exception; it always indicates activity, in our experience.

LABORATORY DIAGNOSIS

The most important feature of the laboratory diagnosis of infectious hepatitis is that the value of different procedures varies with the stage of the disease. This is shown in table 4. Perhaps the most striking example is bilirubinuria, one of the best tests early in the disease but of almost no value later on, because of an apparent increase in the renal threshold to bilirubin.[14] Thus it is usually negative even though the serum bilirubin level is still elevated.

Where specialized laboratory facilities are not available the most satisfactory diagnostic methods are the methylene blue or the strip test for bilirubinuria, the acetone icterus index, the sulfobromophthalein sodium dye retention and the quantitative urobilinogen test. These suffice for the average case. If feasible, the addition of either the cephalin cholesterol flocculation or the thymol turbidity test and Ducci and Watson's modification of the van den Bergh [5] is to be much desired. It is best to routinely employ a relatively small number of tests which are frequently repeated and whose significance is well understood rather than to use a large number of confusing procedures.

COMMENT

There can be little doubt that acute and chronic hepatitis due either to the virus of infectious hepatitis or to other etiologic agents is a common condition. As we have previously pointed out,[2a] the liver is probably involved to a greater or less extent in many acute infections. This is particularly true of virus infections, which tend to be systemic rather than localized and usually involve many of the systems of the body. Delayed convalescence may be due in certain instances to unrecognized hepatic pathologic factors. Similarly, there are a variety of agents that may produce a chronic hepatitis. This disease is probably the unrecognized explanation for many vague gastrointestinal complaints [15] and for certain cases of chronic fatigue.

Prior to the war the clinical picture of hepatic disease except in its severer forms was vague and incomplete. The symptomatology of the nonicteric forms of hepatitis was almost unknown and seldom recognized. This situation, fortunately, has changed.[2a, b] We have developed a relatively clear idea of the clinical picture produced by at least one type of infection of the liver. As described in this paper, the diagnosis of infectious hepatitis can usually be made with reasonable certainty. The application of this knowledge to the diagnosis of other forms of hepatitis should lead to a more frequent recognition of the importance of the liver in disease and as a result to more effective treatment.

SUMMARY

The most valuable diagnostic methods and diagnostic criteria, in our experience, have been described for infectious hepatitis in its various stages. Persistent evidence of hepatic abnormality in the presence of symptoms consistent with the disease is the basis of diagnosis. In regard to laboratory methods, there is much variation in the value of tests in relation to the stage of the disease. The relative value of different procedures is indicated.

TABLE 4.—*Diagnostic Value of Various Liver Function Tests in Different Stages of Infectious Hepatitis*

	Prodromal	Acute Icteric	Acute Nonicteric	Chronic
1 Bilirubinuria	++	+	++	+
2 Bilirubinemia	++	++	++	++
3 Flocculation tests	++	+	++	+
4 Sulfobromophthalein sodium	+	0	++	++
5. Urobilinogen.	+	+	++	++
6 Phosphatase .	±	+	++	+
7 Prothrombin . . .	0	±	0	0
8 Cholesterol esters	±	±	++	++
9 Albumin globulin ratio	+	+	++	–

Key: ++, most valuable, +, limited value; 0, not of value

THERAPEUTIC AGENTS IN LIVER DISEASE

A Review of Medicinal Agents

DWIGHT L. WILBUR, M.D.
San Francisco

The functions of the normal and diseased liver are surprisingly little affected by the action of drugs which are not hepatotoxic. In fact, in regard to the activity of drugs the striking action is that of the liver on them and not of the drugs on the liver, and one might well entitle this paper "The Effect of the Liver on Drugs" rather than "The Effect of Drugs on the Liver." Clark[1] has well summarized the situation by stating that "few means are known by which the functions of the liver can be stimulated or aided by means of drugs."

In the index of "A Manual of Pharmacology" Sollmann[2] has listed under the title, "Liver," only three subjects, namely "antianemic preparations," "extract-saline" and "liver of sulfur." A brief review of the subject indicates clearly that, with the exception of certain specific drugs used in the treatment of diseases such as amebiasis which affect the liver, there are no drugs which are specifics in the treatment of disease of the liver. In fact, the essence of the principles of treatment of hepatic disease is to dilute and eliminate toxic agents if they are known and to restore the nutritional state of the liver by supplying to it by whatever means possible and in adequate quantities all essential nutritive materials. It has been clearly and repeatedly demonstrated that the reaction of the liver to toxic agents varies with the previous diet of the subject and with the chemical composition of the liver. Therefore, principal consideration will be given in this review to recent studies of the relationships of various amino acids, vitamins, proteins and enzymes to diseases of this organ, which has been so aptly termed the "servant of the body."

NUTRITIONAL SUBSTANCES AS MEDICAL AGENTS

Fatty Liver—Relation of Lipotropic Factors—Methionine, Choline, Lipocaic and Inositol.—Grossman and Ivy[3] have pointed out that deposition of fat in the liver may result from an increase in the rate at which fat is supplied to the liver or by a decrease in the rate at which the liver is able to dispose of fat. Substances such as choline, inositol and lipocaic, which prevent some of these types of fatty livers, are known as lipotropic factors. In the transport of fat from the liver phospholipids are necessary. Of these substances lecithin, in which choline is the nitrogenous base, appears to be the principal phospholipid concerned. Choline may be supplied in the diet as choline or as phospholipid, or the body may synthesize it if sufficient compounds containing labile methyl groups are available. Methionine, a sulfur-containing amino acid, can supply this labile methyl factor and is therefore an extremely important substance.

These facts explain why fatty livers of choline deficient animals can be cured by adding choline or methionine to the diet or increasing the casein percentage in it and further explain why choline, lecithin, methionine and similar substances have been used in the treatment of hepatic disease.

In some cases of fatty liver, such as those resulting from certain poisons (toxipathic hepatitis) lipotropic substances are only partially effective in overcoming the fatty changes because factors independent of the choline supply tend to glut the liver with fat or to handicap it in the disposal of fat.

Methionine: Reports in the literature[4] indicate clearly that this amino acid is of great usefulness in the prevention and treatment of various forms of hepatic disease and particularly that of fatty liver in the experimental animal. However, reports of the use of it in hepatic disease in man are less striking and with a few exceptions not encouraging. Fagin and his associates[5] studied by chemical analysis the liver of patients with cirrhosis and came to the conclusion that the administration of amino acids to patients with alcoholic cirrhosis results in a decrease in hepatic fat and an increase in the percentage of protein; these effects are due to the methionine content of the amino acids. In the treatment of a case of accidental poisoning with carbon tetrachloride (30 to 40 cc.), Beattie and his group[6] promptly administered methionine, at first by mouth and subsequently intravenously, with prompt subsidence in the size and tenderness of the liver and in symptoms of impending hepatic coma. Subsequently, in 2 cases of carbon tetrachloride poisoning and in a large number of patients with trinitrotoluene hepatitis Eddy,[7] following the use of methionine, reports results which are encouraging and suggests that the amino acid is of clinical value.

Although 10 of the 30 patients with acute hepatitis due to trinitrotoluene observed by Eddy[7] had severe damage to the liver and although in previously reported cases the mortality rate had been 30 per cent, there were no deaths in this series. Methionine was used in doses of 2 Gm. four times a day, and although the evidence is circumstantial, this method of treatment is certainly worthy of further study.

Further clinical evidence that methionine may be useful in toxic forms (toxipathic hepatitis) of hepatic disease was present by Beattie and Marshall,[8] who in a preliminary report suggested that the occurrence of damage to the liver during arsenical treatment can be either prevented or minimized by the administration of methionine or by the use of casein digests rich in this amino acid.

The possible usefulness of methionine in the treatment of infectious hepatitis has naturally aroused great interest because of the widespread occurrence of this disease. To date the results are not particularly encouraging. Wilson, Pollock and Harris[9] gave methionine in 5 Gm. doses daily to alternate patients

in a group of 100 men with the disease. Clinical and laboratory studies revealed no significant therapeutic effect of methionine. Subsequently Hoagland and Shank[10] in a careful study of 200 patients with the disease gave to 16 of them 5 Gm. of a racemic mixture of methionine in 200 cc. of isotonic solution intravenously on admission and daily for ten days. There were no adverse effects and no clinical or laboratory evidence that the disease was perceptibly influenced by this form of treatment.

Choline: For reasons already mentioned it is apparent that choline might be of therapeutic value in hepatic disease. Because of the great variability in the clinical course of such disease and particularly of cirrhosis, convincing evidence of the therapeutic value of substances such as choline is difficult to obtain, and at present the results of such treatment are largely confined to impressions. For example, Russakoff and Blumberg[11] placed patients with cirrhosis on a low fat Patek dietary regimen supplemented with 1.5 to 6.0 Gm. of choline chloride daily. Since no untoward effects of postprandial oral administration of the substance was noted, and since 7 of 9 patients who were treated adequately improved, the observers were of the opinion that the results were highly suggestive of a beneficial effect. Barker[12] also has advocated the use of choline chloride in cirrhosis in daily doses of 1.5 Gm. administered in the form of a 10 per cent elixir.

In their excellent study previously mentioned Hoagland and Shank[10] gave to 25 of their patients with infectious hepatitis 5 mg. of choline hydrochloride in divided doses on admission and daily thereafter for ten days. No effect which could be attributed to choline therapy was noted in the clinical course of the disease.

Reports that choline has produced hyperchromic anemia in dogs lead to the fear that similar results might occur in man. However, in one patient with cirrhosis and macrocytic anemia to whom Wilson and Castle[13] fed choline chloride in a dose of 17 mg. per kilogram of body weight daily for seventy days, the anemia was not intensified but in fact the blood improved.

Lipocaic and Inositol: Lipocaic is a lipotropic substance of pancreatic tissue effective in preventing the fatty liver which develops in depancreatized dogs maintained with insulin. Inositol, a component of the vitamin B complex, is also an essential component of the phospholipid, lipositol.

Both of these substances would appear to warrant clinical trial in those forms of hepatic disease in which deposition of fat is a significant factor, but to date reports of their use singly in the treatment of hepatic disease in man have not appeared.

Protein: The potential therapeutic value in hepatic disease of certain amino acids such as methionine has already been discussed. Brief mention should be made of the use of protein substances in this connection. Until recent years an adequate intake of protein in the treatment of hepatic disease was not stressed, since most efforts were to flood the tissues with carbohydrate, particularly dextrose, because of the remarkable effect of this substance in the prevention and control of hepatic damage in the experimental animal. Further impetus was given to this form of therapy by the development of hydrolysates of protein which permitted the administration intravenously of all of the essential amino acids in large amounts (i. e., "amigen," Mead Johnson & Company; "parenamine," Frederick Stearns & Company).

Ravdin[14] has pointed out that the essential elements of the optimum diet for the treatment of disease of the liver are high caloric content (approximately 3,000 calories), a minimum of 14 per cent and as much as 30 per cent of protein, 70 per cent of carbohydrate and a minimum of fat. He has further emphasized that an unbalanced high carbohydrate diet may lead to a high lipid as well as glycogen concentration in the liver and that such a liver would be as vulnerable to hepatic injury as if its glycogen content was low.

Most diets now prescribed by medical authorities for the treatment of hepatic disease and insufficiency contain 150 to 250 Gm. of protein daily, and it is recommended by them that as much of this amount of protein be administered orally as possible and the balance be administered intravenously.

Watson[15] has made the suggestion that pasteurized beef serum is a possible source of protein in the treatment of hepatic disease. He states that the substance is sold at ridiculously low prices as tankage for hogs; that mixed with tomato juice it is very palatable, and that beef serum albumin is undoubtedly an excellent protein from the point of view of nutrition in general and as far as the provision of methionine and the protection of the liver are concerned.

Extensive studies, particularly by Whipple and his associates,[16] on plasma protein regeneration in experimental animals have revealed facts worthy of clinical consideration. They showed among other things that when the nitrogen of the diet was provided by certain mixtures of the ten amino acids essential for growth in the rat plus aminoacetic acid, given intravenously at a rapid rate, plasma production in the dog was good. When the same mixture was given subcutaneously at a slower rate it seemed to be somewhat better utilized. However, oral feedings of the same amino acids were definitely better utilized and were associated with a lower urinary nitrogen excretion than were the same amino acids given parenterally. Furthermore, after a period of dietary deficiency, when a missing "essential" amino acid was returned to the mixture or when a complete protein was fed, some delay in the output of new plasma protein was observed. There sometimes was a lag of two or three weeks before the output became normal.

In other interesting studies of protein metabolism and the liver, Whipple and his group[17] have developed the concept of "dynamic equilibrium" of the proteins. This concept visualized a ready flow of plasma proteins out of the circulation into the tissues and vice versa.

[17] Fink, R. M., and others: Plasma Protein, Metabolism Normal, and Associated Shock: Observations Using Protein Labeled by Heavy Nitrogen in Lysine, J. Exper. Med. **80:** 455-475 (Dec.) 1944.

As has been stated,[18] "it is their belief that the liver is concerned with the production of many of the plasma proteins and with the maintenance of the normal levels of these proteins in the circulating blood. The liver in other words is the 'master organ' for various protein metabolic activities. It stores protein, it makes protein (fibrinogen, prothrombin, and other globulins and albumins) and it aggregates amino acids and other nitrogenous materials coming from the gastrointestinal tract into protein." It is, moreover, indicated that the liver is concerned directly or indirectly with the production of new hemoglobin.

Further data to support the thesis of "dynamic equilibrium" of tissue and plasma proteins is presented by Fink and his associates,[17] who suggest that there is in the normal animal an active tissue mass of protein about equal in size to the mass of plasma protein, since the rapid dilution phase (of administered amino acids containing lysine tagged with heavy nitrogen in the epsilon amino position) seemed to end near the 50 per cent level.

Further evidence of the close relation of hepatic function and protein intake is indicated by the studies of Goettsch, Lyttle, Grim and Dunbar,[19] which indicate that animals placed on a diet extremely low in protein and experiencing hypoproteinemia as a result seemed to show impairment in hepatic function that paralleled the decline in serum albumin. In a study indicating anatomic changes in the liver following protein starvation, Elman and his group [20] have demonstrated that the histologic appearance of the liver as well as its content of nitrogen and glycogen depend on the intake of carbohydrate and that, while a protein deficient diet will lead to a protein deficient liver, carbohydrate intake exerts a great influence on the histologic appearance. When the carbohydrate intake is high the cells are large, contain little protein and present a rarefied appearance of the cellular protoplasm often called hydropic degeneration. After a fast (absence of carbohydrate), the liver is just as deficient in total nitrogen because it is smaller, and the microscopic picture may be called one of atrophy; the cells are smaller, the nuclei closer together and the cytoplasm dense.

Brief mention should also be made of the protein catabolic process which accompanies trauma—particularly that of fractures, burns and certain types of infections, including meningitis and virus pneumonia—and in which disease of the liver may play a prominent role. It has been pointed out [21] that the vigor of protein catabolism appears to depend on the two factors of intensity of stimulus and the capacity of the organism to respond to the stimulus.

The high loss of protein associated with this catabolic process appears not to be appreciably spared during its height by large quantities of protein, whether they are administered orally or intravenously as amino acids. The extent of this catabolic process is indicated by the studies of Cuthbertson [22] in 6 patients in whom an average loss of bodily nitrogen following fractures was more than 220 Gm. Expressed in terms of protein this would be about 1,400 Gm. or in terms of normal muscle protoplasm 15 pounds (6.8 Kg.). The period of protein loss continued for an average of 35.6 days.

All these studies among others indicate definite and probable relationship between the liver and protein metabolism in the normal person and of hypoproteinemia and altered metabolism in patients with disease of the liver. It seems clear that an adequate and probably high intake of complete proteins is desirable in the treatment of hepatic disease, that the substances are probably better utilized when administered by the natural oral channel and that during the interval when sufficient amounts cannot be so administered the intravenous administration of amino acid preparations is advantageous.

Carbohydrate: The usefulness of large amounts of carbohydrate as a therapeutic measure in disease of the liver is so well established and so universally recognized that no further discussion of it is needed in this review.

Vitamin A: The metabolism of vitamin A and its precursor, carotene, and of the liver are intimately related. In hepatic disease the plasma values for vitamin A are usually lower than normal and the amount stored in the liver less than the normal. These changes come about as a result of a less than normal dietary intake of the vitamin, inadequate absorption of it and/or interference with normal hepatic cell function. It seems unlikely that administration of the vitamin would benefit patients with hepatic disease. In an effort to study this problem Abels and his collaborators [23] gave to 8 patients with carcinoma of the gastrointestinal tract and with impaired hepatic function 50,000 to 150,000 U. S. P. units of vitamin A daily for seven to twenty days. The plasma level of vitamin A was raised in 2 instances only, although the administration of vitamin A was made parenterally in 7 of the 8 cases. To date it seems likely that the only clinical value of the study of vitamin A metabolism in hepatic disease is as a diagnostic test.

Ascorbic Acid: Clinical evidence is lacking that the metabolism of ascorbic acid is significantly altered or that the vitamin is of therapeutic value in hepatic disease. Some experimental data exist, however, to indicate that ascorbic acid may exhibit a protective action. In guinea pigs, at least, Beyer [24] convincingly demonstrated that ascorbic acid protected the liver from the hepatotoxic effect of hydrazine to a significant degree.

MEDICINAL AGENTS WHICH PRODUCE TOXIC EFFECTS ON THE LIVER

One of the most striking and clinically significant functions of the liver has to do with its detoxifying function. In this respect the liver seems to be the chief organ of defense of the body. In the process of detoxifying certain substances and thus preserving the organs as a whole, the liver may suffer variable amounts of damage. Brief mention should be made in this review of the effect of certain therapeutic agents which may at times be hepatotoxic.

As was pointed out by Clark,[1] toxic agents may be handled by the liver in various ways—they may be excreted unchanged in the bile, broken down by the liver, synthesized or conjugated to form innocuous compounds or stored. Indeed, the duration of action of many drugs, including barbiturate and sulfonamide compounds, is limited by the detoxification of them in the liver. The conversion of ammonium salts into urea is the most important detoxifying action of the liver.

[24] Beyer, K. H.: Protective Action of Vitamin C Against Experimental Hepatic Damage, Arch. Int. Med. 71: 315-324 (March) 1943.

Chester Jones [25] has listed some of the hepatotoxic agents which are frequently used therapeutically or which are commonly used industrially and to which, therefore, the livers of many persons may become exposed. Among the former may be listed arsenicals, gold, bismuth, cinchophen and sulfonamide compounds; and among the latter carbon tetrachloride, trinitrotoluene, tetrachlorethylene and phosphorus. Anesthetic agents such as chloroform, tribromoethanol and ether also are hepatotoxic, as is alcohol.

Brief mention should be made of the effect of some of those hepatotoxic agents. In general the significant factors in this process, in addition to the dose of the toxic substance administered, are the sensitivity of the person or his liver to the drug and the nutritive state of the patient. As Jones [25] has pointed out, the caloric adequacy in the diet, the inclusion of various substances, such as proteins, specific amino acids and vitamins, particularly those of the vitamin B complex, and the exclusion of excessive amounts of fat are factors that undoubtedly modify the response of the liver to noxious substances.

Arsenic.—There is much controversy concerning the relation of arsenotherapy for syphilis and hepatic damage. Of interest among reports related to this subject are the following: Riddell and Anderson [26] were of the opinion that in the case of neoarsphenamine and oxophenarsine hydrochloride, at least, the effect was dependent primarily on individual sensitivity rather than on the quantity of the drug administered. In a study of jaundice in the Canadian Army, Mitchell [27] observed that the incidence of clinical jaundice in those patients receiving arsenotherapy for syphilis was over thirty-six times as high as that in the group of syphilitic patients not receiving arsenical therapy. Incidentally, jaundice occurred three times as commonly in patients treated with neoarsphenamine as in those treated with oxophenarsine hydrochloride. The possibility was raised that preexisting unrecognized infectious hepatitis without jaundice may have been a factor in producing the high incidence of jaundice following arsenotherapy.

Annegers and his colleagues [28] suggested that the oral administration of dehydrocholic acid may aid in counteracting the hepatotoxic action of oxophenarsine hydrochloride.

Sulfonamide Drugs.—The relation of sulfonamide therapy to hepatic disease is still not clear but is worthy of consideration because of the wide use of these drugs. Sulfonamide therapy may occasionally result in direct damage to the liver, as indicated by the studies of Menten and Andersch,[29] who observed toxic necrosis and toxic central necrosis of the liver in children with liver disease who had had sulfonamide therapy. However, not all the evidence is unfavorable, for there is considerable experimental data to show that sulfonamide compounds are not only not harmful but may actually be helpful in preventing damage to the liver. Machella and Higgins [30] studied rats to which carbon tetrachloride had been given and concluded that administration of sulfanilamide to rats with hepatitis did not increase the damage to the liver. In fact, it appeared to lessen the damage. Furthermore, sulfanilamide did not impede regeneration of the liver after the dosage of carbon tetrachloride was discontinued, nor did it produce any detectable injury to the livers of animals with obstructive jaundice. Further studies by Forbes and Evans [31] indicated that sulfanilamide apparently exerted a protective action against damage to the liver from the inhalation of chloroform in rats and rabbits. Clinical observations which bear out these experimental observations have been made by Peterson, Deutsch and Finland,[32] who reported that in patients with acute hepatitis and bacterial infection, sulfonamide therapy was almost always accompanied with improvement in hepatic function paralleling the improvement in the underlying infection. Furthermore, some severe toxic effects other than those of direct injury to the liver were unusually frequent in patients with portal cirrhosis and intercurrent infections. Caution should be exercised in the administration of sulfonamide compounds in patients with severe portal cirrhosis of the liver. Sulfadiazine produced fewer reactions than did sulfathiazole.

Cinchophen.—Annegers and his associates [33] have presented evidence that the administration of cinchophen to a susceptible animal may produce decided temporary depression of the synthesis and secretion of cholic acid and, further, that despite recovery of this function death could occur. This observation indicated that some other unrelated vital function of the liver had been impaired by the drug.

Quinine and Quinacrine Hydrochloride.—Anderson and his associates [34] have indicated that in the experimental animal there is in the liver some agent that is evidently active in the metabolic destruction of quinine, and that underlying hepatic disease may seriously alter the therapeutic effects of the drug.

The effects of quinacrine hydrochloride ("atabrine *di*-hydrochloride") in the liver are indefinite. Annegers and his associates [35] indicated that in some human beings damage to the liver seems to occur, but to date the available information is not striking. However, in another study of the toxic effects of this drug Butt and his associates [36] indicated that at high dosage levels it does not have any particularly significant hepatotoxic action in man.

Thiouracil.—Experimental evidence has been presented by György and Goldblatt [37] to indicate that the addition of thiouracil to a cirrhosis-producing synthetic diet has a preventive effect on the development of cirrhosis in rats. It is suggested that the protective action of thiouracil and perhaps also of sulfonamide compounds on the liver is indirectly achieved through their effect on the thyroid which lowers the rate of metabolism of methionine.

EFFECTS OF BILE SALTS

In association with a summary of the effects of drugs on the liver brief mention should be made of the recent studies of the effect of certain drugs on the flow of bile. In an editorial comment on the matter of cholecystogogues, choleretics and cholepoietics, Ivy [38] advocated the adoption of cholecystogogue as a term referring to an agent or agency which causes or promotes the evacuation of the gallbladder. Choleresis he considered a general term meaning an increase in the output of bile, while cholepoiesis in his opinion is a general term referring specifically to the process of formation of bile by the liver. Various modifications of these terms may be used to indicate the specific effect of any substance. The administration of a mixture of sodium taurocholate and glycocholate (extract of ox bile U. S. P., or natural bile salts) causes a choleresis, cholaneresis and cholesteroleresis. Of particular interest to physicians will be the observations of Ivy and his associates [39] that aloe and podophyllum resin in the form of "Carter's little liver pills" have no detectable effect on the formation of bile by the liver, the evacuation of the gallbladder and the passage of bile into the duodenum.

HORMONES AND THE LIVER

Inactivation of Hormones.—The normal liver plays a significant role in inactivating certain hormones. The close relation of the inactivational functions of the liver and the nutritional status of it is indicated by the following observation. The normal liver plays an important role in inactivating estradiol, while the livers of animals deficient in thiamine or riboflavin failed to inactivate the substance. However, livers of animals depleted of pyridoxine, pantothenic acid, biotin or vitamin A retained their ability to inactivate the substance.[40]

The liver is said to play a significant role in the inactivation of corpus luteum hormone, serum gonadotropin, epinephrine and diethylstilbestrol.

Thyroxin and Desiccated Thyroid.—The relation between hyperthyroidism and the hormones of the thyroid gland and the liver are not entirely clear. There is little question of the occurrence of hepatic disease in some cases of hyperthyroidism. The changes in the liver may be classified as acute degenerative lesions, atrophy (generalized or focal) and cirrhosis. Increasing evidence is accumulating to indicate that factors other than the thyroid hormone enter into the hepatic changes. Recently Drill and Gunn [41] have shown that rats fed sufficient amounts of thyroid to produce pronounced loss of weight over a period of seventeen to eighteen days did not show any significant changes in the liver when compared to normal animals on the same diet. Similarly those rats fed the gland for eighty-one days and receiving a supplement of yeast concentrate revealed normal histologic structure of the liver. Drill and Gunn suggested that previous reports of hepatic damage experimentally produced by feeding thyroid were at least in part due to the type of diet fed (i. e., one low in vitamin B content). On the other hand, McIver and Winter [42] performed experiments which indicated that anoxemia is significant in the production of varying degrees of hepatic injury in animals made hyperthyroidic with thyroxin. Control rats given thyroxin without being subjected to anoxemia showed only low hepatic glycogen and no structural lesions in the liver.

Epinephrine.—Injections of epinephrine produce curves of blood sugar which are lower in patients with disease of the liver than in normal persons. Recent studies by Bradley [43] have indicated that the substances may also have an effect on hepatic blood flow. This worker, who developed a technic for estimating hepatic blood flow in man, found that in 6 of 7 cases the estimated hepatic blood flow increased, occasionally as much as 300 per cent following the intramuscular administration of 0.4 to 1.0 cc. of epinephrine.

EFFECT OF MISCELLANEOUS AGENTS

Gamma Globulin.—In January 1945 Stokes and Neefe [44] presented definite evidence that gamma globulin is capable of preventing or attenuating infectious hepatitis when administered to exposed persons during the incubation period of the disease. The possibility was indicated also that the substance might be of therapeutic value if given early in the preicteric stage of hepatitis. This effect was subsequently verified in another study by Stokes and his associates [45] and by Paul and Havens.[46] In adults a dose of 10 cc. of gamma globulin and in children a dose of 0.08 cc. of gamma globulin per pound (0.5 Kg.) of body weight given intramuscularly proved effective.

Liver Extract.—It seems natural that extracts of liver in various forms should have been used in the treatment of disease of this organ, although the rationale for the use of them may be a little obscure.

It appears evident that the effect of liver extract in hepatic disease is not specific. The frequent occurrence of macrocytic anemia in chronic hepatic disease has been used as an argument in favor of use of liver extract in these diseases, and more recently it has been stated (Hoagland and Rivers [47]) that in some cases of infectious hepatitis the use of crude liver extract has

strikingly improved the appetite of patients and has doubled their caloric intake in several weeks.

In general the results of such treatment have been obscure also. However, in recent years some promising results have been obtained in the treatment of cirrhosis of the liver by means of crude liver extract administered intravenously in large amounts (Hoagland[48]). Fleming and Snell[49] have also reported cases of cirrhosis treated with crude liver extract along with usual methods with results suggesting a good effect. To a group of 34 patients with infectious hepatitis Hoagland and Shank[10] administered daily for ten days a specially prepared aqueous extract of Cohn's fraction G of liver in amounts of 10 cc. diluted to 50 cc. with isotonic solution of sodium chloride. No adverse effects were noted and no significant alteration was observed in the average gain in weight or period of hospitalization.

Agents Used in the Treatment of Pruritus.—Medicinal measures for the relief of the pruritus of jaundice, including ergotamine tartrate, calcium salts, calomel, histamine, insulin and sodium thiosulfate, are well known, and no further comment on them is warranted here. However, it should be pointed out that in occasional instances when the use of these measures, and particularly that of ergotamine tartrate, fails or is contraindicated intravenous injections of procaine hydrochloride may give striking relief. In doses of 20 cc. of a 0.1 per cent solution (1 Gm.) in 1,000 cc. of isotonic solution of sodium chloride given intravenously slowly, Lundy[50] has found that the substance sometimes affords dramatic temporary relief for several hours (two to four or more).

Agents Used in the Control of Ascites and Edema.—Diuretics such as mersalyl, mercurophylline injection, potassium nitrate and ammonium chloride are often useful adjuncts in the control of ascites and anasarca occurring in hepatic disease, but as far as is known, in the doses used for these purposes they have no significant action on the liver.

Colloidal Thorium Dioxide.—Yater and Coe[51] in a summary of 274 cases in which colloidal thorium dioxide ("thorotrast") was used as a diagnostic measure concluded (1) that hepatosplenography was of value in the study of cirrhosis, metastases and abscess of the liver; (2) that there had been observed no evidence of latent radioactivity, depression of spleen or blood-making function, increased susceptibility to infection or development of cancer at the site of infection, and (3) that hepatosplenography was of little value in the study of splenomegaly. In cirrhosis the diagnostic criteria set up consisted of a diffuse mottling or reduced density of the liver; in metastases, rounded areas of lessened density often surrounded by a halo of increased density, and in abscess, a rounded area of reduced density, usually without a halo.

Histamine.—In further studies of estimated hepatic blood flow Bradley[43] found that histamine in doses of 0.36 to 0.60 mg. given intramuscularly caused little change in 4 instances; a transient effect similar to that caused by ephinephrine was twice observed.

Gelatin.—Considerable thought has been given to the use of gelatin as a substitute for plasma protein in the treatment of burns, shock and hepatic disease. The rapid development during the war of dried plasma, the preparation of serum albumin in a form suitable for intravenous use and the easy availability of pooled wet plasma have rendered almost needless such substitutes for plasma as gelatin and acacia.

With reference to gelatin it might be pointed out that in dogs Whipple and his associates[52] have observed that gelatin administered by vein for one to two weeks in doses of 3 to 17 Gm. per kilogram of body weight usually caused serious disturbances, including inhibition of protein production in the blood, signs of intoxication, much loss of weight and even death. For the first few days after its administration the adverse effects did not appear. In fact, the reaction was decidedly variable and the site of damage was not clear. Histologic changes were not noted, but it was considered that the liver might be the site of deleterious action by gelatin.

In a group of 6 patients with extensive carcinomatosis, Brunschwig and others[53] infused intravenously gelatin solution containing 14 to 27 Gm. daily for three to ten days. The injections were well tolerated, and slight increases in urea nitrogen excretion occurred in 5 of the patients. The variability in these reported results may be explained perhaps by the fact that gelatin is not a chemical entity but a highly variable product made from a number of different materials treated in a great variety of ways, and consequently it is probable that considerable variation in the utilization and toxicity of various samples may occur.

Diet and Hepatic Tumor Formation.—Another phase of evidence clearly demonstrates the importance of adequate nutrition in protecting the liver against hepatotoxic agents. The well known effect of the aniline dye butter yellow (P-dimethylaminoazo benzine) in producing hepatic tumors in rats can be effectively modified by the use of protective foods including liver, yeast, milk and mixtures of certain grains. In 1944 Opie[54] demonstrated that fat in the diet accelerates the production of hepatic lesions by this dye and that when the quantity of fat in the diet is small few tumors are produced.

SUMMARY

There are no drugs which are specific in the treatment of hepatic disease. The principal effect is that of the liver on drugs and not of drugs on the liver. Dietary substances are of greater value in the prevention than in the treatment of hepatic diseases. They are also of greater value in acute trophopathic hepatitis than in chronic toxipathic hepatitis, in which their value appears limited.

Until specific drugs are available, the principal forte in the treatment of hepatic disease will continue to be along the general lines of increasing the resistance of and the restorative powers of the liver (1) by supplying it with abundant quantities of essential nutritive materials, (2) by diluting, neutralizing or eliminating hepatoxic substances and (3) by physical rest of the affected person.

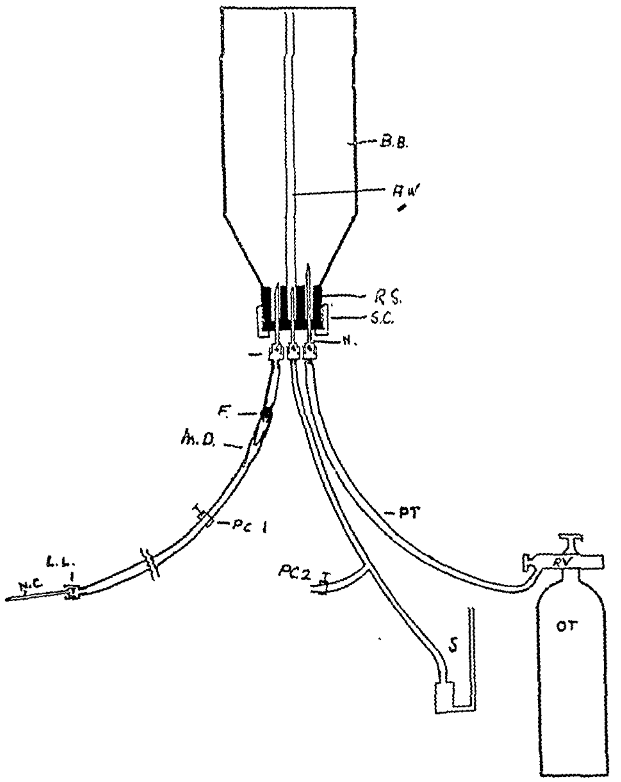
Clinical Notes, Suggestions and New Instruments

THE TREATMENT OF SHOCK BY AORTIC TRANSFUSION DURING THORACIC OPERATIONS

EARLE B. KAY, M.D.
and
VERNON D. HACKER, M.D.
Cleveland

Peripheral arterial transfusions have been shown to be of value experimentally in the study of shock by Kohlstaedt and Page.[1] Gardner[2] has proved their usefulness in its clinical control. Arterial transfusions may have occasional value in thoracic surgery. Uncontrollable hemorrhage during thoracic operations is a potential hazard. If this complication should occur it may be impossible to provide sufficient blood intravenously after hemostasis to sustain life. It may be difficult or occasionally impossible to obtain veins for venipuncture if the patient is in shock. Unnecessary time may be lost in attempting venipuncture. Even though blood can be provided in adequate amounts the dangers of pulmonary edema and right sided cardiac failure are ever present when blood is given too rapidly intravenously.



Apparatus for arterial transfusion: B.B., blood bottle; A.W., airway; R.S., rubber stopper; S.C., screw cap; N., needles (size indicated); L.L., luer locks; F., filter; M.D., Murphy drip; P.T., pressure tubing; P.C. 1 and 2, pinchcocks; S., sphygmomanometer; R.V., reducing valve; O.T., oxygen tank and N.C., needle or cannula in patient's artery. With pinchcock 1 closed and pinchcock 2 open the oxygen is turned on to 1 liter per minute. This oxygenates the blood as shown by the change in color from dark red to bright red. Pinchcock 2 is slowly closed. The pressure in the blood bottle is controlled during the transfusion by adjusting pinchcock 2.

The mortality rate from injuries of the mediastinal vessels is high. Though the hemorrhage may be surgically controlled, death may result from loss of blood and shock. If the state of shock persists unduly long permanent damage may result from anoxemia of the brain, kidneys and liver. Heretofore, treatment has consisted mainly of intravenous replacement and cardiorespiratory stimulants. The aorta lends itself readily for the administration of blood as an emergency procedure during operations within the chest. Furthermore, oxygenated blood can be provided, thus reducing the factor of anoxemia. The following case report demonstrates the benefit possible from such a procedure.

REPORT OF CASE

At 3 o'clock in the morning of Nov. 16, 1946 a Negro man aged 60 was admitted to the accident room of St. Luke's Hospital. He was semiconscious, inebriated and in shock. He had received a stab wound in the first intercostal space adjacent to the sternum approximately thirty minutes prior to entry. The pulse was feeble and soon disappeared. The blood pressure was unobtainable. The right side of the chest was dull to percussion. Faint breath sounds could be heard anteriorly near the sternum. There was evidence of a mediastinal shift to the left. Fluoroscopic examination revealed the right chest to be opaque and the mediastinum shifted to the left. Plasma was given immediately without significant benefit; this was followed by a blood transfusion. Though the blood pressure and pulse were unobtainable the patient continued to have rapid gasping respirations. From the position of the stab wound it was felt that the innominate artery or the superior vena cava had been injured.

He was taken to the operating room and a thoracotomy performed. As a result of the profound shock and alcoholic consumption it was possible to introduce an intratracheal tube under light anesthesia. Controlled ventilation was maintained by the anesthetist during the operative procedure, mainly with oxygen.

The right side of the chest was entered anteriorly through the bed of the second rib. The sternum was transected to allow adequate exposure of the superior mediastinal vessels. There was no bleeding from the wall of the chest when the incision was made. It was noted that the internal mammary artery had been severed approximately 1 inch (2.5 cm.) from its origin by the injury. Blood was slowly oozing from the cut section. This artery was immediately ligated. The entire right side of the chest was filled with clotted and fluid blood, which was removed. No other source of bleeding from the mediastinal vessels or from the right lung could be found. The patient still had no pulse or blood pressure, and the heart was observed to be beating rather slowly, as in failure. As an emergency procedure an oxygenated transfusion was given into the ascending aorta through a size 18 needle. The first portion of the transfusion was given by oxygen pressure and the latter by pressure from a hand pump. Five hundred cubic centimeters of blood were given in three minutes. There was no bleeding from the aorta after the removal of the needle. Immediately following the aortic transfusion a pulse was palpable, and as the chest wall was closed the blood pressure was 80 systolic and 50 diastolic.

The postoperative course was characterized by drowsiness, diarrhea and incontinence for the first three days. It was impossible to determine the urinary output during this time. There was no urinary output on the fourth and fifth postoperative day, while the daily fluid intake was 3,000 cc.

Chemical analysis of the blood on the fourth postoperative day showed the nonprotein nitrogen to be 182 mg. per hundred cubic centimeters, the creatinine 14.1 mg. per hundred cubic centimeters and the carbon dioxide combining power 36.2 volumes per cent. The serum protein level was 6.8 Gm., the chlorides 554 mg. and the sugar 141 mg., per hundred cubic centimeters. The nonprotein nitrogen increased to 219 mg. per hundred cubic centimeters on the seventh postoperative day.

It was felt that the renal damage and failure were probably due to anoxemia of the kidneys during the period of shock. The possibilities of previous renal disease and of reaction to transfusion were also considered. Appropriate treatment was administered for the renal failure. On the sixth postoperative day the urinary output was 670 cc., and the amount increased daily thereafter. The nonprotein nitrogen and blood creatinine values gradually decreased, so that at the time of discharge on Dec. 7, 1946 the nonprotein nitrogen was 45.5 mg. and the creatinine 1.8 mg., per hundred cubic centimeters. Urinalysis six days

2. Gardner, W. J.: The Control of Bleeding During Operation by Induced Hypotension, J. A. M. A. **132**: 572 (Nov. 9) 1946.

postoperatively showed a concentration of 1.015, a trace of albumin, and an infrequent red blood cell but no casts. Subsequent microscopic analyses of the urine revealed no abnormalities.

A check-up examination Jan. 22, 1947 showed the patient to be in good health and asymptomatic except for paresthesia in both hands. A urea clearance test at this time was 68 and 74 per cent of normal.

A diagrammatic sketch of the apparatus for providing oxygenated arterial transfusions under pressure is shown.

SUMMARY

An injury to the right internal mammary artery with an exsanguinating hemorrhage is reported. The blood pressure and pulse of the patient were unobtainable for approximately one hour. Operative hemostasis and restoration of the blood pressure by an intra-aortic transfusion of oxygenated blood was performed. The postoperative convalescence was complicated by evidence of uremia.

It is felt that intra-aortic transfusions of oxygenated blood may be lifesaving in certain emergencies arising during thoracic operations.

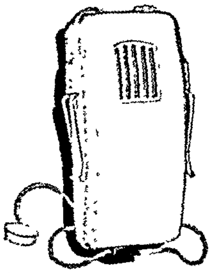
Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

WESTERN ELECTRIC HEARING AID, MODEL #64, ACCEPTABLE

Manufacturer: Western Electric Company, 195 Broadway, New York.

This instrument is a two unit hearing aid, the microphone and amplifier in one pack and the batteries in the other. The plastic case containing the amplifier and microphone has the volume control and combination switch-tone-control set in the top of the case. Cords for batteries and receiver are connected by a plug at the bottom of the case. Three battery cases are available, one for light duty, 22.5 volt batteries, and two larger cases for heavier duty. Three tone control settings are possible and are indicated on the switch by one, two and three dots.



Western Electric Hearing Aid #64.

Dimensions and Weight

Weight.—Hearing aid alone, 4.2 ounces (119 Gm.).

Small battery case and batteries, 3.5 ounces (99 Gm.).

Medium battery case and batteries, 7.5 ounces (213 Gm.).

Large battery case and batteries, 8.1 ounces (230 Gm.).

Dimensions.—Microphone and amplifier, 4¼ by 2½ by 1 inches (8.2 by 6.4 by 2.5 cm.).

Small battery case, 2 15/16 by 2 7/16 by ⅝ inches (7.4 by 7.0 by 1.6 cm.).

Medium battery case, 3 11/16 by 2 9/16 by 1 1/16 inches (9.3 by 6.6 by 2.8 cm.).

Large battery case, 3 5/16 by 2½ by 1⅜ inches (8.4 by 6.4 by 7.0 cm.).

Battery	Measured Voltage	Measured Current
A. 1½ volts	1.5 volts	80 milliamperes
B. 22½ volts	22.5 volts	1.3 milliamperes
B. 30 volts	30 volts	2.2 milliamperes

Acoustical Gain

Acoustical gain measurements were made using the regular procedure followed in the Council's acceptance tests of other hearing aids and described in the *Journal of the Acoustical Society of America*, vol. 16, No. 1, pages 38-44. Acoustical gains measured in this way are known to be somewhat lower than the free field measurements used in obtaining the data submitted by the manufacturers. When allowance is made for the difference in the two methods, the measured values are in reasonable agreement with those submitted by the manufacturers. Typical results of the measurements of the Council are tabulated as follows:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096 cycles
Full volume							
Tone control set at 1	23	37.5	37	40	43	44	36.5 decibels
Tone control set at 3	4	14	24	25	34	36	34 decibels

Approximate values of maximum pressure levels, at four frequencies with the instrument attached to coupler with volume of 2 cc., control set at full gain and at No. 1 tone setting, are shown as follows:

Frequency	Input Level	Maximum Output Level
600 cycles	65 decibels	95 decibels
1,024 cycles	65 decibels	97 decibels
2,048 cycles	65 decibels	95 decibels
3,100 cycles	70 decibels	103 decibels

Intelligibility tests were made and showed satisfactory performance. The Council on Physical Medicine voted to include the Western Electric Hearing Aid, Model #64, in its list of accepted devices.

TELEX HEARING AID MODEL #22 ACCEPTABLE

Manufacturer: Telex, Inc., Minneapolis.

This instrument, Model #22, is self contained. The battery compartment in the lower half of the case is covered by a snap-back. The plastic case is composed of three parts. The wearing clip is on the back of the case, opposite the microphone grill. The receiver cord plugs into the top end of the case.

The two-position tone control switch and the combination on-off and volume control switch are placed at the upper corners. One magnetic receiver, a Telex A, was supplied.

Dimensions and Weight.—Dimension 5¼ by 2⅜ by ⅞ inches (13.3 by 6.0 by 2.2 cm.). Weight 6.8 ounces (193 Gm.).

Batteries	Measured Voltage	Measured Current
A 1½ volts	1.3 volts	65 milliamperes
B 30 volts	27.5 volts	0.56 milliamperes

Acoustical Gain.—Measurements were made of the gain in decibels in the sound pressure level set up attached to a 2 cc. coupler over the pressure levels at the microphone placed in the face of a 16 by 8 inch (40.6 by 15.2 cm.) baffle. The input level at each frequency was 0.02 dyne per square centimeter. The following figures, in decibels, are typical of the results obtained when the volume-control was turned full-on at various frequencies:

Frequency	256	512	1,024	1,200	2,250	3,100	4,096 cycles
Tone controls							
#1 (upper)	43.0	50.5	55.0	56.5	59.0	48.0	40.0 db.
#2 (lower)	33.0	42.5	51.5	54.0	56.5	47.5	40.0 db.

Approximate values of maximum pressure levels, at four frequencies observed on a 2 cc. coupler with volume control set for full gain and the number 1 (upper) tone setting:

Frequency	Input Level	Maximum Output Level
600 cycles	55 decibels	102 decibels
1,024 cycles	65 decibels	104 decibels
2,048 cycles	50 decibels	103.5 decibels
2,250 cycles	50 decibels	105.5 decibels

Intelligibility tests were made with a normally hearing person so placed that the speaker could barely be heard with the hearing aid turned off. These tests indicated satisfactory performance.

The Council on Physical Medicine voted to include the Telex Hearing Aid, Model #22, in its list of accepted devices.

ESSENTIAL FATTY ACIDS AND INFANTILE ECZEMA

Experimental studies have demonstrated that certain unsaturated fatty acids are essential for the maintenance of normal skin in several species of animals.[1] Whether or not this is true for man has not yet been convincingly shown. However, some indication that these substances might also play some role in human nutrition was first observed in patients with infantile eczema.[2] Certain babies afflicted with this condition appeared to be benefited when vegetable oils rich in unsaturated fatty acids are added to the diet in comparatively large amounts. Subsequent clinical studies in infants and children have both confirmed and denied the favorable effect claimed, perhaps the bulk of evidence being confirmatory, however.

Hansen and his co-workers[3] have reported further extensive studies on eczema in 225 patients, the majority of whom were under 2 years of age. The patients were first carefully examined and a comprehensive record was made of the locations, nature and severity of lesions. Fresh lard was then given in amounts of 1 to 2 ounces daily either alone, as a spread, or mixed with sugar, peanut butter or some other palatable material. Raw linseed oil or corn oil was also used for some patients. The supplementary fat feeding was continued for one to three months until a reliable clinical evaluation of the response could be made. The response was considered "good" if the cutaneous manifestations either completely disappeared or nearly cleared. Otherwise the response was graded "fair," "poor" or "none." Simultaneously, changes in the degree of unsaturation of the fatty acids of the serum were determined, since earlier work had suggested that the serum fatty acids of patients with eczema tend to be less unsaturated than those of control subjects.[4]

The clinical response indicated a definite benefit in the majority of cases, especially in infants and younger children. Of 148 patients treated there were 60 in whom the results were good to excellent, 51 in whom the results were fair to good and 37 in whom the response was either poor or lacking. With respect to the response of different age groups, it was found that 40 per cent of the adults showed "poor" or no response, whereas only 36 per cent of the children and 12 per cent of infants responded unfavorably.

Studies on the blood lipids in 171 patients confirmed the earlier observation that the serum fatty acids are less unsaturated than those of control subjects, especially in infants. Whereas the iodine number of the serum fatty acids of normal subjects averaged about 100, that of the patients averaged from 80 to 95, depending on their age. The differences were found to be statistically significant. The serum iodine numbers tended to increase to normal values as the clinical condition improved following supplementation of the diet with fat.

The author's conclusion thus appears warranted that supplementary fat, such as lard or certain vegetable oils rich in unsaturated fatty acids, is definitely beneficial in the majority of cases of eczema, particularly in infants. However, they wisely emphasize that such therapy is not a complete substitute for good general and local therapy but should be regarded as a valuable adjunct to the accepted modes of treatment.

CONGENITAL TUBERCULOSIS

Hughesdon[1] has tabulated and classified 35 cases of congenital tuberculosis which have appeared in medical literature from 1935 to 1945 inclusive. Beitzke, quoted by Hughesdon, analyzed all published cases and classified them according to the site of the primary complex. He found 61 cases of proved congenital tuberculosis with pathologic lesions and 40 cases in which tubercle bacilli were found in the fetus without histologic changes. His criteria of proof of congenital tuberculosis in the infant were that (1) the tuberculous nature of the lesions in the infant must be proved; (2) a primary complex in the fetal liver is proof of the congenital nature of the tuberculous changes, since it can have arisen only from tubercle bacilli in the blood of the umbilical vein; (3) if there is no primary complex in the liver, the infection is congenital only if (*a*) tuberculous changes are found in the fetus in utero or at birth or a few days after birth and (*b*) in a child who lives longer than a few days if extrauterine infection can be excluded with certainty, the child being immediately separated from the mother and kept in an environment free from tubercle bacilli.

Apparently, therefore, during approximately the last seventy years 115 proved cases of congenital tuberculosis have been described in the literature including both cases in which pathologic lesions were present and those in which only a tuberculous bacillemia occurred. To these cases Hughesdon adds 4 cases of congenital tuberculosis which were observed in a children's hospital in England. The fact that 4 cases of congenital tuberculosis have been observed in one children's hospital during the last twelve years suggests that intrauterine or intrapartum infection of the fetus with tubercle bacilli may occur more frequently than hitherto believed. Infection of the fetus, according to Hughesdon, may take place when the mother's tuberculous lesion is minimal or even undetectable by present methods of investigation. This is consistent with the view that tuberculous bacillemia may occur at any time during a period of activity of an existing tuberculous focus, no matter how small. Tuberculous lesions in the placenta can release tubercle bacilli into the fetal blood spaces of the placenta, with subsequent infection of the fetus by way of the umbilical vein. Tubercle bacilli may also be liberated from a lesion in the placenta or membranes into the amniotic fluid, and the fetus may be infected by inhalation or ingestion of the fluid. Congenital tuberculosis is not necessarily fatal, as demonstrated by the author's reports of cases 3 and 4, in which death occurred at the ages of 13 and 27 months respectively and in which the diagnosis of congenital tuberculosis was not made until the postmortem examinations. In all 4 cases reported by the author there were primary complexes in both liver and lungs.

---

[1] Hughesdon, Mary K.: Congenital Tuberculosis, Arch. Dis. Childhood **21:** 121 (Sept.) 1946.

The true estimate of the incidence of congenital tuberculosis could be obtained only by routine postmortems of children dying from all causes.

Current Comment

POSTGRADUATE COURSES FOR PHYSICIANS

An important aid to the physician desiring to keep abreast of the progress of medicine is the offering of continuation courses throughout the country. Semiannually the Council on Medical Education and Hospitals of the American Medical Association publishes a list of postgraduate courses offered to physicians for the ensuing six months. In this issue of THE JOURNAL (page 626) and in next week's issue the courses listed cover the period from July 1, 1947 to Jan. 15, 1948. More than eight hundred courses offered by numerous institutions and organizations are listed. The medical schools take a prominent part in presenting these courses. In addition a number of courses, while not given by medical schools, will employ the facilities of medical schools. The wide usefulness of these listings is indicated by the tremendous demand for reprints, numbering regularly about a thousand per month. The institutions and individuals participating in these programs are rendering a great service to the profession and to the physician veterans.

THE HOSPITAL IN THE REHABILITATION OF THE HANDICAPPED

One of the great contributions of war medicine was the rehabilitation program in the service hospitals now being carried into the Veterans Administration hospitals. The fracture, the gunshot wound, the head and peripheral nerve injury and paraplegia received an integrated program of surgical treatment, physical therapy and conditioning, and graduated military activity, which prepared the patient for return to duty. When the residual disability prevented him from satisfying the demands of military service, educational and prevocational training was provided to prepare him for return to civil employment. Thus, whereas much of the rehabilitation service in World War I was carried on after the patient was discharged from the hospital, in World War II every attempt was made to obtain complete physical restoration and vocational preparation before he left the hospital. The advantage of an integrated and continuous program of this sort was of especial value with amputations. At the army and navy amputation centers, a five point program was followed. This included (1) the psychologic preparation of the patient, (2) a rational plan of surgical treatment which employed a few standard procedures such as the Syme amputation, the below the knee amputation, the Stokes-Gritti amputation and the above knee amputation, (3) the shrinking of the patient's stump with appropriate exercises of the stump and body musculature, (4) the selection and fabrication of a modern prosthesis and (5) of especial importance, the systematic and intensive training of the amputee in the use of this prosthesis. Prevocational and vocational training were carried out within the hospital framework so that discharge from the hospital meant return to an independent economic and social existence. During the war from 17,000 to 18,000 amputees received the benefit of this type of service. During the same period approximately 120,000 civilians lost their limbs from congenital deformity, disease and accidental injuries, 67,000 of them in industry. Yet few of these persons have enjoyed the advantage of an integrated and continuous program, either within the hospital or after discharge from the hospital. There is need for the establishment of rehabilitation centers where the amputee and all severely handicapped can receive the follow-up care which will lead to their return to employment. This need is being met in a small number of instances by the establishment of outpatient facilities designed to provide a limited program of after-care. More such centers are needed. Rehabilitation, after discharge from the hospital, however, is not enough. The within hospital program, as demonstrated in the service hospitals, is of paramount importance. Many hospitals are already equipped to carry on such a program and require only an organization to implement it. Such an organization can be developed by the creation of a rehabilitation committee consisting of one or more physicians interested in rehabilitation, the physical therapist, the occupational therapist, the social worker and the rehabilitation representative of the state rehabilitation commission. This committee can establish policies, supervise the program in action and carry on liaison with public agencies, thus providing a rapid turnover for its chronic cases and a full measure of treatment leading toward reemployment of its disabled patients. In a large hospital the services could be delegated by the committee to a rehabilitation officer, preferably a physician trained in physical medicine.

ARTERIOSCLEROSIS IN YOUTHS

An increasing number of reports on arteriosclerosis in infants and young adults has contributed recently to the accumulating evidence that this disease is not the inevitable consequence of senescence but the result of various endogenous and exogenous factors acting on the blood and the vascular tissues.[1] Recent observations on juvenile atherosclerosis deal mainly with coronary arterial disease in soldiers between the ages of 18 and 40 in the United States, England and Germany.[2] In the great majority of these cases the first and fatal attack of coronary obstruction was not preceded by any warning symptoms pointing to the presence of coronary sclerosis. As these soldiers had passed a more or less thorough medical examination, their deaths from partly advanced coronary disease is a rather sad commentary on the state and value of the available diagnostic methods. This realization is the more depressing as there is general agreement among the authors that coronary sclerosis in young persons is definitely more common than is usually assumed and that the incidence of this serious vascular disease has been on the increase during the last decades. Little definite information is available concerning the etiology of juvenile coronary sclerosis. French and Dock mentioned that 73 of their 80 patients had some degree of obesity pointing to a disturbance of the fat metabolism as the causative mechanism. Poe, however, noted only 1 of his 9 patients as obese. Newman characterized all of his 50 English soldiers with coronary occlusion as well built or obese. Infections of the throat and respiratory organs, as well as rheumatic and scarlet fevers providing a toxic or allergic mechanism, were mentioned by Newman and others. In a 6 weeks old infant that died of coronary sclerosis a hyperergic reaction developed on the basis of a drug allergy of the mother during pregnancy and caused the calcification and thrombosis in the coronary artery.[3] In many other cases of fatal coronary or general arteriosclerosis in infants chronic renal disease, hypervitaminosis D, hyperparathyroidism, hyperadrenalism and thromboangiitis obliterans were listed as causative factors.[4] A vasotoxic effect of nicotine associated with excessive smoking of cigarets was cited by Meessen and by Holzer and Polzer[5] as a significant etiologic factor in juvenile coronary sclerosis. The histologic changes observed in sclerotic coronaries in youths have been identical with those seen in persons of more advanced age. Thus, calcifications were not less common in the sclerosed vessels of the young than they are usually found in those of the old. Since it was noted that the early developmental stage of coronary sclerosis is often associated with an imbibition of the vascular wall by a fat free edematous fluid, fibrinoid swelling and active vascularization of all layers of the wall, an allergic origin of juvenile coronary sclerosis may not be infrequent. The not infrequent occurrence of fatal juvenile arteriosclerosis provides a forceful reminder that the prevention and therapeutic control of arteriosclerosis represents one of the most urgent problems of medicine.

DETERMINATIONS OF BLOOD VOLUME

In a procedure for the determination of blood volume, red cells containing radioactive iron are injected; the blood volume is determined from the degree of dilution of the injected cells and the hematocrit value. The radioactive red cells are formed in a suitable host following the oral administration of radioactive iron.[1] The blood volume was determined by this procedure on a series of 28 patients in a variety of clinical conditions. The volume differed in many cases from values obtained by the more generally used dye method by as much as 1 and 2 liters.[2] There appears to be no definite agreement as to which procedure yields the more reliable values. In the newer method the cell volume is determined directly and the whole blood volume is calculated from the hematocrit; in the other scheme the blood plasma volume is determined directly and the whole blood volume is calculated from the hematocrit. The larger values obtained by the dye method suggest that some of this dye is lost, perhaps through phagocytosis by the reticuloendothelial cells, by adsorption on the plasma proteins or in other less obvious ways. A rather constant difference in the blood volumes of healthy human subjects and in laboratory animals as obtained by the two methods has been attributed to the measurement by the radioactive red cell method of only "rapidly circulating plasma volume." However, estimations of blood volume by the use of carbon monoxide and with a dye method have been found to agree within about 10 per cent in healthy human and animal subjects.[3] *The determination of blood volume would* appear to be valuable in ascertaining the state of hydration of the body and the rate of formation of plasma constituents such as albumin. Until methods are more fully worked out, caution must be exercised in the interpretation of small variations in the values obtained.

ORGANIZATION SECTION

MEDICAL DEPARTMENTS OF THE ARMY AND NAVY

An Analysis of Pending Federal Legislation, Prepared by the Bureau of Legal Medicine and Legislation

Shortly after the Eightieth Congress convened, legislation was introduced to reorganize the Medical Departments of the Army and Navy. In the Senate two bills were introduced by the chairman of the Senate Committee on the Armed Services, S. 334 to establish the Medical Associated Sciences Corps in the Medical Department of the Navy and S. 504 to revise the Medical Department of the Army.

In the House several bills were introduced with similar objectives on which hearings were held. Following such hearings revised bills were proposed, H. R. 3215, introduced by the chairman of the House Committee on Armed Services, which would revise the Medical Departments of the Army and Navy, and H. R. 1943, introduced by Representative Smith of Maine, which would establish a permanent Nurse Corps and a Women's Medical Specialist Corps in the Medical Department of the Army.

Other bills have been introduced to provide for the procurement of physicians and surgeons in the Medical Department of the Army, S. 1143 and H. R. 3174, and to provide additional inducements to physicians and surgeons to make a career of the United States naval services, S. 1197 and H. R. 3254.

Army Medical Service Corps.—Title I of H. R. 3215 as reported to the House, which is similar to title I of S. 504, would establish in the Medical Department of the Regular Army a Medical Service Corps consisting of the Pharmacy, Supply and Administration Section, the Medical Allied Sciences Section, the Optometry Section and such other sections as the Secretary of War may deem necessary. The Secretary of War will be authorized to determine from time to time the strength of this corps.

The corps will consist of officers in the grade of second lieutenant to colonel, inclusive. There will be a chief of the corps appointed by the Secretary of War and assistant chiefs similarly designated who will be chiefs of sections.

Appointments from sources other than the Regular Army or its active reserve will be made from persons who are graduates from accredited schools of pharmacy, optometry or other schools or colleges who possess degrees in sciences allied to medicine or such other degrees as may be approved by the Surgeon General. A person holding a doctorate degree in sciences allied to medicine at the time of appointment may be credited with an amount of service equal to three years, for the purpose of determining grade, position on promotion list, permanent grade seniority and eligibility for promotion.

The Pharmacy Corps and the Medical Administrative Corps will be abolished. Officers of the Regular Army who hold commissions in the Pharmacy Corps will be transferred in grade to the Medical Service Corps. Persons holding temporary appointments or commissions in the Army of the United States permanently assigned or detailed to the Medical Administrative Corps, the Pharmacy Corps or the Sanitary Corps will be automatically assigned or detailed to the Medical Service Corps.

Navy Medical Service Corps.—Title II of H. R. 3215 would establish a Medical Service Corps in the Medical Department of the Navy with sections similar to those proposed for the corresponding corps in the Medical Department of the Army. The authorized strength of the corps will be 20 per cent of the authorized strength of the Medical Corps of the Navy. It will consist of staff officers in the grades of ensign to captain, inclusive. With certain exceptions, all appointments in the corps will be in the grade of ensign from those persons serving as commissioned warrant or warrant officers of the Hospital Corps of the Regular Navy and from other persons who possess such physical and other qualifications as may be prescribed by the Secretary of the Navy. Appointments from sources other than the Regular Navy will be from persons who are graduates of accredited schools of pharmacy, optometry or other schools or colleges with degrees in sciences allied to medicine or such degrees as may be approved by the Surgeon General. Persons holding a doctorate degree in sciences allied to medicine may be appointed in the grade of lieutenant (junior grade).

The Hospital Corps of the Navy.—Title III of H. R. 3215 provides that the authorized strength of the Hospital Corps of the Navy shall equal 3.5 per cent of the authorized enlisted strength of the Navy and Marine Corps and will consist of the following grades and ratings: commissioned warrant officers and warrant officers, Hospital Corps, and enlisted men classified as chief hospital corpsmen; hospital corpsmen, first, second and third class; hospital apprentices, first and second class. These classifications in enlisted ratings will correspond respectively to the enlisted ratings, seaman branch, of chief petty officers; petty officers, first, second and third class, and seamen, first and second class.

The President will be authorized to appoint as many warrant officers, Hospital Corps, as he may deem necessary from the ratings of chief hospital corpsman and hospital corpsman, first class. Warrant officers now in the Hospital Corps of the United States Navy and those hereafter appointed therein will have the same rank, pay and allowances allowed to other warrant officers.

Medical Associated Sciences Corps—Medical Department of Navy.—A bill introduced by the chairman of the Senate Committee on Armed Services, S. 334, proposes to establish the Medical Associated Sciences Corps as a constituent part of the Medical Department of the Navy. This corps would consist of not more than 205 officers of the grade of medical associated scientists who will have the rank of captain, commander, lieutenant commander, lieutenant or lieutenant (junior grade). Such officers will be staff officers, subject to all provisions of law relating to the advancement in rank and retirement of officers of the Medical Corps.

All appointments to the grade of medical associated scientists will be made by the President by and with the advice and consent of the Senate from male citizens of the United States who shall have received a doctorate degree in such sciences related to medicine as the Secretary of the Navy shall determine.

Army-Navy Nurses Act of 1947.—Another bill, H. R. 1943, which has already passed the House and Senate, would establish a permanent Nurse Corps and a Women's Medical Specialist Corps in the Medical Department of the Regular Army and a permanent Nurse Corps as a component part of the Medical Department of the Navy. The Women's Medical Specialist Corps would consist of a Dietitian Section, a Physical Therapist Section and an Occupational Therapist Section. These sections would perform such services as may be prescribed by the Secretary of War. The authorized strength of this corps will be in the ratio of nine tenths of a member thereof to every thousand persons in the total authorized strength of the Regular Army but not less than a minimum authorized strength as follows: 24 officers in the permanent commissioned grade of major and 385 other officers in the permanent commissioned grades of captain to second lieutenant, inclusive.

The report of the Senate Committee on the Armed Services pointed out the necessity for this legislation and summarized the principal features as follows:

"Under present legislation both army and navy nurses are occupying temporary commissioned rank. With the ending of the war emergency and without new legislation, the members of the Army Nurse Corps and the Women's Medical Specialist Corps in the Medical Department of the Regular Army, and of the Navy Nurse Corps, will revert back to relative rank and to the prewar scale of pay allowances, which, under the Pay Readjustment Act of 1942, began with the sum of $1,080 per annum and increased to the top pay of $1,800 per annum for a person who had served twelve years, and after which there were no increases. Major Gen. Norman Kirk, Surgeon General of the Army, Col. Florence A. Blanchfield, superintendent of the Army Nurse Corps, and Admiral Clifford A. Swanson, Surgeon General of the Navy, testified, during the course of the hearing on H. R. 1943, that a reversion to the prewar pay scale would result in a complete dissolution of the Army and Navy Nurses' Corps.

"Failure to enact appropriate legislation would place the medical branches of the armed services in the impossible position of attempting to compete with civilian nursing agencies that offer much more attractive salaries and less personal deprivation.

"Summary of principal features of H. R. 1943:

"1. Army and navy nurses and personnel of the Women's Medical Specialist Corps of the Army would be commissioned on a permanent status, the same as all male officers.

"2. Pay, leave, money allowances for subsistence and rental of quarters, mileage and other travel allowances, benefits and emoluments would be the same as for male officers.

"3. Provisions for promotion would be the same as for male officers except that army nurses and specialists above the rank of captain and navy nurses above the rank of lieutenant would be chosen by the selection boards.

"4. Retirement provisions would be the same as for male officers except that the retirement age is reduced to 55 years in the ranks above captain in the Army and above lieutenant in the Navy, and to 50 years in the rank of captain or below in the Army and lieutenant or below in the Navy.

"5. The proposed legislation would establish similar provisions for nurses of both the Army and Navy with exactly the same pay and allowances.

"6. The bill would not result in increased per capita expenditures over those maintained during the wartime period."

Procurement of Army Medical Officers.—Companion bills are pending to provide for the procurement of physicians and surgeons in the Medical Department of the Army, S. 1143 and H. R. 3174. This legislation proposes that the active duty base and longevity pay of each commissioned officer of the Medical Corps with less than thirty years' active service will be increased by $1,200 per year. The Secretary of War will be authorized to designate as specialists qualified commissioned officers. Any person so designated will be entitled, in addition to the pay and other allowances otherwise provided by law, to an increase of 25 per cent of his base and longevity pay while on active duty. There would be established in the Medical Department of the Regular Army four professorships in medicine, surgery, neuropsychiatry and preventive medicine. Appointments will be made by the President by and with the advice and consent of the Senate, and commissions will be given in the Medical Corps of the Regular Army to physicians and surgeons who have been certified as specialists by an American Specialty Board recognized by the Advisory Board for Medical Specialties and the Surgeon General of the Army. Such persons will be appointed in a grade not above that of colonel.

The Secretary of War will be authorized to employ civilian physicians in such numbers and for such periods of time as he may deem necessary to serve with the Medical Department of the Army. Persons so appointed would receive pay, according to the grade in which appointed, from $3,640 to $9,800. Any person so employed could be designated by the Secretary of War as a medical or surgical specialist, in which case he would receive, in addition to his basic pay, an allowance equal to 25 per cent of such pay subject to the limitation that the pay plus the allowance may not exceed $11,000.

The Secretary of War would also be authorized to employ physicians on a temporary full time, part time or fee basis, with the limitation that no temporary full time appointment may be made for a period of more than ninety days.

Naval Medical Officer Procurement Act of 1947.—Companion bills are also pending to provide additional inducements to physicians and surgeons to make a career of the United States naval service, S. 1197 and H. R. 3254. This legislation proposes that, in addition to pay, allowances or emoluments that they are otherwise entitled to receive, commissioned medical officers of the Navy Medical Corps will be paid the sum of $100 for each completed month of active service. Such sum will not be included in computing the amount of increase in pay authorized by any other provision of law or in computing retired pay. The total amount which may be paid to any one officer by virtue of this proposal may not exceed $36,000.

The Surgeon General of the Navy will be authorized to designate as specialists qualified commissioned Medical Corps officers of the Regular Navy and of the Naval Reserve who are certified as specialists by an American specialty board recognized by the Surgeon General. Officers so designated will receive an increase of 25 per cent of their base and longevity pay while on active duty. Such increase in pay will not be included in computing the amount of increase in pay authorized by any other provision of law or in computing retired pay.

Original appointments may be made by the President, by and with the advice and consent of the Senate, of permanent commissioned grades, with rank not above that of captain, in the Medical Corps of the Navy in such numbers as the needs of the service may require. Such appointments will be made only from civilian medical and surgical specialists who have been certified as specialists by an American specialty board recognized by the Advisory Board for Medical Specialists and by the Surgeon General of the Navy. The physicians and surgeons so appointed will be carried as additional numbers in rank but will not increase the authorized number of commissioned officers of the Medical Corps of the Regular Navy.

Washington Letter

(From a Special Correspondent)

June 11, 1947.

Support of Socialized Medicine Being Probed

A house expenditure subcommittee of which Representative Harness, Republican of Indiana, is chairman, is investigating charges that public funds were being spent to promote socialized medicine. The probe was part of congressional investigation of government publicity and alleged "propaganda" activities, which opened with accusations from Congressmen and denials by federal officials. Under discussion were "workshop health conferences" held in 1945 and 1946 in Chicago, St. Paul and Jamestown, N. D., which reportedly discussed public health insurance and other subjects and adopted resolutions favoring such insurance. The committee heard testimony that officials of various government agencies helped plan the conference.

Threatens Loss of German Science Secrets

Elimination of the appropriation for the Technical Information Bureau of the Department of Commerce may lose for the United States the benefits of almost the entire wartime output of German science. At Karlsruhe, Germany, and at 15 Canal street S.W., Washington, D. C., are warehouses crammed with millions of pages of scientific reports collected after the war by American investigating teams. The 250 experts working on the reports overseas may have to return home at once or risk being stranded, and the staff engaged on the reports here will have to be dismissed. Foreign Minister Molotov estimated the value of the scientific information at ten billion dollars. Documents already examined are reported to contain information worth billions to American industry and science.

Advocate Modernization of Hospitals

Representative Mary T. Norton, Democrat of New Jersey, has introduced a House bill asking Congress to let federal funds be used to modernize all nonprofit hospitals in Washington. This would be somewhat in conflict with House action last year in deciding that Washington should have a modern hospital center in which Emergency, Garfield and Episcopal hospitals were to participate. The House had voted down a recommendation that federal grants be authorized for hospitals not in the center. Mrs. Norton's bill would restore original Washington hospital improvement features sought by Federal Works Agency and local hospital officials.

Dr. Spencer Resigns as Chief of National Cancer Institute

The resignation of Dr. R. R. Spencer, chief of the National Cancer Institute, U. S. Public Health Service, has been announced. He will devote his full time to training young physicians in diagnosis and treatment of cancer. Surgeon General Thomas Parran announced that Dr. Leonard A. Scheele, assistant chief of the institute, is successor to Dr. Spencer, who is shedding heavy administrative work for training and research.

Laboratories to Explore Nuclear Science

The program outlined in the Atomic Energy Commission's report to Congress last January is reportedly being followed through establishment of a nationwide chain of laboratories to study continuously every field of nuclear science. The laboratories will, in addition to military and power uses of atomic energy, study the production and dissemination of radioactive isotopes for medical and other scientific research and study and experiment in radiation.

Compensation for Injured Federal Workers

The Senate Civil Service Committee is to get legislation seeking to increase compensation of federal employees seriously injured in line of duty. At present a totally disabled person gets a maximum of $116 per month, but the new legislation would increase this by at least a third. It is contended that government salaries have increased 35 per cent in the last few years.

Bureau of Information

LOCATION OF PHYSICIANS

Virginia Shuler
Chicago

This is the third of a series of charts showing the trend in locations of physicians from April 1946 to January 1947; the first series appeared May 17, page 301, and the second series May 31, page 465.

"As to physician distribution Minnesota is quite well provided for as far as medical service is concerned. There are no areas in the state at the present time where needs for physicians are distressing. In most areas there is at least one physician within a radius of 20 miles; and there are no localities at present where one must travel farther than that for medical attention.

"At the present time there are some 1,000 young physicians, mostly returned medical officers, who are in training in Minnesota—that is, who are doing graduate work or taking continuation courses, residencies or fellowships. These young men will be released beginning about July 1 of this year and will continue to come out for the next two years. We presume that at least 50 per cent of these men will remain in this state and will meet whatever urgent demands there are for more physicians."

MR. R. R. ROSELL,
Executive Secretary,
Minnesota State Medical Association,
496 Lowry Medical Arts Building,
Saint Paul 2.

"The listing of physicians by county and the applying of the number per county against the county population in order to arrive at a ratio is as misleading in North Dakota as it is in other states. On this basis a number of our counties show but 1 active physician to 3,000 or more population. Actually in a number of cases the population within these counties live within a reasonably short driving distance of large medical centers which have 1 physician to each 999 or less population. Be that as it may, North Dakota is in actual need of additional physicians. A percentage of these are needed each in the rural communities for the obvious local care which may be afforded by the general practitioner, and also in the medical centers, to relieve the burden at those points caused by the actual desire of rural people to go to such centers for their more serious ailments. As the rural people continue to prefer the larger trading center, not only for the purpose of receiving medical care but also for the purpose of receiving other services and as a place to transact most of their ordinary business affairs, to that of the one time prosperous small village, the hope of extending medical services into the true rural community diminishes. Migration of physicians during the past year has been slight but continues to show the trend of movement from the rural community to the urban community. This no doubt will continue until sufficient physicians are available to satisfy the full demand in the medical centers, at which time the law of supply and demand should cause a greater spreading of doctors through the rural communities. According to recent surveys North Dakota has a somewhat adequate supply of larger general hospitals. The rural communities, however, could benefit greatly if money available under the Federal Hospital Construction Act were to be used in the construction of small buildings in the nature of a community health center where public health services could be combined with office space and facilities for a rural doctor with the inclusion of six to ten beds. Such an arrangement would make possible the distribution of public health services to the community, encouragement for a physician to settle in the community and facilities for emergency care and probably obstetric care in the local community. This in turn of course will relieve the burden on the overcrowded hospitals in the nine larger medical centers."

Dr. L. W. Larson,
Secretary,
North Dakota State Medical Association,
Little Building,
Bismarck, N. D.

"All of our cities and towns seem to be adequately cared for, but some of our smaller villages need the services of a physician acutely

"As is true anywhere else, people in South Dakota are willing to travel to the larger centers of population where they can receive the best medical care but sometimes are unable to do so because of the conditions of the roads In the spring and winter it is sometimes impossible for a sick person to go even 10 miles to see his physician"

Medical Legislation

STATE LEGISLATION

California

Bills Passed.—S 808, which passed the house May 29, to amend the **health and safety code**, proposes to require every licensed physician and surgeon or other person engaged in prenatal care of a pregnant woman, or attending such woman at the time of delivery, to obtain a blood specimen of such woman at the time of the first professional visit or within ten days thereafter and to submit such sample to an approved laboratory for a laboratory test for syphilis S 1026, which passed the senate May 26, 1917, to amend the **education code**, proposes to prohibit any instruction in sex relations, marital problems or like questions at any time prior to the twelfth grade The proposal would further require that where such instruction is given it shall be conducted by a duly licensed physician and handled as an individual activity retaining the normal relationship of physician and patient

Bills Enacted.—A 229, which has become chapter 377 of the Laws of 1947, makes the testing of the sight and **hearing of school children** mandatory rather than permissive and provides that such tests shall be made only by duly qualified supervisors of health, such term not being defined S 569, which has become chapter 360 of the Laws of 1947; provides an appropriation of $250 000 to be expended by the University of California to conduct additional research on the origin, prevention and **cure of cancer.**

Connecticut

Bills Passed.—S 133, which passed the house May 28, to amend the law relating to **osteopathy**, proposes to establish higher minimum requirements and more rigid supervision of the professional practice of osteopathy in the state S 169, which passed the house May 26, relating to the **practice of chiropractic**, proposes to require applicants for certification without examination to be graduates of approved schools, to meet the requirements of the state board of healing arts and to have three years of practice in the state in which they are licensed immediately prior to an application for a Connecticut license, except that persons discharged from the armed forces may have had three years of practice immediately prior to their induction

Florida

Bills Passed.—H 312, which passed the house May 23, to amend the law relating to the membership of the **state board of health**, proposes to authorize other than doctors of medicine to be members thereof, that is, "a licensed practitioner under the laws of the state of Florida of one of the healing arts for the treatment of human ills other than a doctor of medicine" H 440 which passed the senate May 29, proposes to make it unlawful for tax collectors in the several counties to issue **state and county occupational licenses** to any person applying for a license to practice medicine in any of its branches unless and until proof of current qualification and competency, as established by certificate or license issued by the state boards duly constituted and legally authorized to determine qualification and competency, be exhibited at the time of making such application

Bills Enacted.—H 253, which became law without approval on May 27, authorizes persons to donate and give their eyes for **eyesight restoration** purposes by last will and testament and authorizes any state, county, district or other public hospital to purchase and provide the necessary facilities and equipment to establish and maintain an eye bank for restoration of sight purposes S 151, which became law without approval on May 26, amends the law relating to the **practice of massage** by redefining the meaning of the practice so as to include the use of electrical apparatus

Michigan

Bills Passed.—H 451, which passed the senate May 29, proposes the enactment of a law requiring the licensing, regulation and **inspection of hospitals** and related institutions and the appointment of an advisory institutional council S 201, which passed the house May 29, proposes to authorize the state commissioner of health to regulate and promulgate rules and regulations controlling the **humane use of animals** for the diagnosis and treatment of human and animal diseases, the advancement of veterinary, dental, medical and biologic sciences, and the testing and diagnosis, improvement and standardization of laboratory specimens, biologic products pharmaceuticals and drugs The proposal would further require that no person, firm or corporation shall keep or use animals for experimental purposes unless registered to do so by the state commissioner of health S 378, which passed the house May 29, proposes to require that all children prior to registration for the first time in any of the public or private schools, kindergartens, day nurseries or any other preelementary schools in the state shall give evidence that they have been **properly immunized** against diphtheria, whooping cough and smallpox Exempted from the act are children whose parents or legal guardian have religious objections to such immunization

Nebraska

Bill Passed.—L B 250, which passed the legislature June 2, proposes to provide for the licensing inspection and **regulation of hospitals** and related institutions within the state and to create a hospital licensing council

Bill Enacted.—L B 389, which was approved May 28, redefines the **practice of chiropody** by adding to the present definition the following words "a person practices chiropody who holds himself out as being able to diagnose, treat, operate, or prescribe for any disease, pain, deficiency, deformity or physical condition of the human foot and who shall either offer or undertake by any means or methods to diagnose, treat, operate or prescribe for any disease, pain, deficiency, deformity, or physical condition of the same" The only limitation on the right to perform certain types of surgery would seem to be the amputation of the foot or toes whereas previously chiropodists were unable to make "correction of deformities requiring the use of the knife"

Pennsylvania

Bill Enacted.—S 335, which has become chapter 128 of the Laws of 1917, amends the **law relating to consumer credit** by providing that the act shall not apply to nonprofit corporations organized under the laws of the state having memberships consisting exclusively of duly licensed physicians, surgeons and dentists operated exclusively for and by their members and engaged in, among other activities, the financing of personal obligations arising from the rendering of professional services by the members of such nonprofit corporations which are limited strictly to medical, surgical, dental, operative, diagnostic and treatment services or nursing and hospital care

Rhode Island

Bill Passed.—H 612, which passed the senate May 28, proposes the enactment of a **hospital survey and construction act** requiring a survey of hospital facilities in the state and the preparation of a program for the construction of additional needed facilities The proposal would also require the appointment of an advisory hospital council and would authorize the director of the state department of health to apply to the Surgeon General for federal funds to assist in either the survey or the construction of new facilities

Texas

Bill Passed.—H 503, which passed the senate May 29, proposes the enactment of a state **hospital survey and construction act** requiring a statewide survey of hospital facilities and the preparation of a program for the construction of additional needed facilities The proposal also requires the appointment of an advisory hospital council and the establishment of regulations for the purpose of obtaining federal funds to assist in survey and construction programs The administration of this proposal would be under a division of hospital survey and construction in the department of health

Wisconsin

Bills Passed.—S 104, which passed the house May 29, proposes regulations for the licensing, inspecting and **regulating of hospitals** within the state S 509, which passed the senate May 27, proposes to authorize cooperative associations to establish and operate **nonprofit plans for sickness care**, including hospital care, for members through contracts with physicians, medical societies, hospitals and others The proposal would further provide that any person covered by such plan should be free to choose for sickness care any medical or osteopathic physician licensed in the state who has agreed to participate in the plan and abide by its terms, and no physician or osteopath shall be required to participate exclusively in any such plan

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28 30. Dr William J Blanton, Juneau, Secretary

American Neurological Association, Atlantic City, Marlborough Blenheim Hotel, June 16 18 Dr Walter O Klingman, 195 Ft. Washington Ave, New York 32, Secretary.

American Physiotherapy Association, Pacific Grove, Calif, July 6-12. Miss Mildred Elson, 1790 Broadway, New York 19, Secretary.

American Urological Association, Buffalo, N Y, Hotel Statler, June 30-July 3 Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn, Secretary.

Idaho State Medical Association, Sun Valley, June 16 19 Dr. William B Handford, Caldwell, Secretary.

Maine Medical Association, York Harbor, Marshall House, June 22-24. Dr. Frederick R. Carter, 142 High St, Portland 3, Secretary.

Minnesota State Medical Association, Duluth, June 30 July 2. Dr. B. B Souster, Lowry Medical Arts Bldg, St Paul 2, Secretary.

Montana, Medical Association of, Missoula, June 26 28. Dr. H. T Caraway, 115 N. 28th St, Billings, Secretary.

National Tuberculosis Association, San Francisco, June 16 19. Dr. F. D. Hopkins, 1790 Broadway, New York 19, Executive Secretary.

New Hampshire Medical Society, Portsmouth, Hotel Wentworth, June 19 20. Dr. Carleton R. Metcalf, 5 South State Street, Concord, Secretary.

Wyoming State Medical Society, Sheridan, June 23 25. Dr. George E. Baker, 226 E. 2d St, Casper, Secretary.

GOVERNMENT SERVICES

ARMY

ANNOUNCE COURSE IN AVIATION MEDICINE

The recall of twenty Medical Corps Reserve Officers annually for a period of ninety days to attend a course of instruction and training in aviation medicine is announced by the War Department.

The course, which will be presented at Randolph Field, Texas, covers the principles and practice of medicine as applied to aviation and the performance of the "64" Physical Examination for Flying. Each graduate will receive a certificate designating him an aviation medical examiner.

Applicants must be under 40 years of age, meet minimum physical requirements for flying and have an efficiency index of 4.0 or above and be not currently designated a flight surgeon or aviation medical examiner. The first class will begin October 6 and extend through December 12. Government quarters will be available at Randolph Field for students enrolled in the course; facilities will not permit quarters for dependents. Applications for this training should be made by letter, accompanied by a copy of the WD AGO 64, "Physical Examination for Flying," to the Office of the Surgeon General, Attention: Military Personnel Division not later than August 15.

TIME EXTENDED FOR REGULAR ARMY COMMISSIONS

All officers and former officers of the Medical and Dental Corps of the Army will have until the end of July to apply for Regular Army commissions, the War Department has announced. Extension of time for applications for commissions for doctors and dentists was granted as a result of shortages in these classifications in the first three increments of the Regular Army Officer Integration Program. Earlier it was announced that sanitary and medical administrative officers with certain specialties would be allowed additional time in which to file for integration.

Any medical or dental officer who is now on active duty or who saw service with the Army during World War II hostilities will be eligible to submit his application to the Adjutant General. Former officers should address correspondence to the Adjutant General, Attention: AGSO-R, Washington 25, D. C. Applications from officers now on active duty may be submitted through military channels.

PUBLIC HEALTH IN JAPAN

The War Department announces that the military government of the Ryukyus on February 10 directed the establishment of leprosariums in the Ryukyus to provide complete quarantine and treatment of persons with leprosy in the communicable stage. It was estimated that there were about 250 leprous persons in the northern Ryukyus who would be confined to the Amami-O-Shima.

Diphtheria immunization for all children in the southern Ryukyus between the ages of 6 months and 10 years is in progress and 11,000 had been immunized by the end of February.

A separate public health department was set up in the northern Ryukyus, which began functioning March 1.

The number of Ryukyuans on relief in February was 42,623, a decrease from 58,000 in December. Increased and stabilized employment, along with tightening of relief requirements, counted for the relief increase.

MEDICAL EXHIBIT OPEN TO PUBLIC

The Exhibit Section of the Army Medical Museum has been expanded and is now open to the public in new quarters on Independence Avenue between 8th and 9th streets S.W., Washington, D. C. New quarters became necessary because of the acquisition of much new material. Exhibits on various diseases, comparative anatomy and embryology are on display, in addition to historical collections of coins, stamps and medical instruments. Current medical topics of interest are in preparation and will be opened to the public from time to time. These will include a large section on tropical diseases, collections of weapons and moulages depicting military injuries. Special sections containing exhibits relating to veterinary medicine and dentistry and other specialized phases of medicine are of particular interest.

PERSONAL

Vernon Tate, Ph.D., honorary consultant to the Army Medical Library and for many years chief, division of photographic archives and research, National Archives, Washington, D. C., will leave the National Archives to become librarian at the Massachusetts Institute of Technology, Cambridge, where he will direct a campaign to increase greatly the scientific holdings of that library.

ARMY AWARDS AND COMMENDATIONS

Colonel James C. Kimbrough

The Legion of Merit has been awarded to Col. James C. Kimbrough, M. C., U. S. Army, for exceptionally meritorious conduct in 1945. As commanding officer of Percy Jones Convalescent Hospital from April 23, 1945 to Dec. 23, 1945, states the citation, by virtue of his farsightedness, initiative, broad experience and attention to duty, he was responsible for the proper reorganization and enlargement of this hospital in the face of rapidly changing situations. Without benefit of previously approved plans he reorganized the hospital so that it fulfilled, admirably, existing as well as future needs. He selected and trained large numbers of personnel to fit the ever varying needs of the hospital. As a result of perseverance, innate affability and desire at all times to help patients, he raised the position of the Percy Jones Convalescent Hospital to the highest attainable, making it a constant source of pride to the Medical Department. Dr. Kimbrough graduated from Vanderbilt University School of Medicine in 1916 and entered the military service July 20, 1917.

Captain Orlo G. McCoy

The Bronze Star Medal has been awarded to Capt. Orlo G. McCoy, M. C., A. U. S., of Canton, Pa., who was battalion surgeon, 253d Armored Field Artillery Battalion, in which position he performed services beneficial to his organization in combat against the enemy from January to May 1945 in Luxembourg, Germany, Belgium and Czechoslovakia. The citation relates that he cared for the sick and wounded and gave expert medical attention to many casualties under fire throughout the battle of Bastogne and other important engagements on both sides of the Rhine. It states, further, that through his exceptional initiative, professional ability and wise counsel Captain McCoy aided greatly in keeping the health and morale of his unit at a high level and made an important contribution to its successful combat operations. Dr. McCoy graduated from the University of Pittsburgh School of Medicine in 1940 and entered the military service Oct. 1, 1942.

Lieutenant Colonel Sidney Vernon

The Bronze Star Medal has been awarded to Lieut. Col. Sidney Vernon, M. C., A. U. S., of Waltham, Mass., who, according to the citation, performed meritorious services on July 15, 1944 as a prisoner of war at Manila, Philippine Islands. By fearlessly requiring Japanese guards to permit him to remove stifling hatch covers from holds, and to rotate groups of prisoners on deck, he undoubtedly saved many Americans from suffocation. Dr. Vernon graduated from the Long Island College Hospital in 1930 and entered the service in July 1941.

NAVY

TRAINING IN MEDICAL ASPECTS OF ATOMIC ENERGY

In cooperation with the Committee on National Emergency Medical Service of the American Medical Association in the formulation of plans for national defense, the Navy is carrying out research and training personnel in the field of radiologic safety.

In December 1946 a six weeks intensive course in radiologic safety for medical officers was conducted at the Navy Department, Washington, D. C., at the Naval Medical Research Institute, Bethesda, Md., and at the Manhattan Engineer District Laboratories and Plants at Rochester, N. Y., and Oak Ridge, Tenn., for the purpose of training key personnel to be used in the indoctrination of additional personnel. Several of those who received the basic training are now receiving advanced training in radiation physics and chemistry, radiologic safety, nuclear physics and allied sciences in civilian institutions.

A number of trained navy medical officers are being used as instructors at the radiologic safety school for line officers which is being conducted at Treasure Island, Calif., and are teaching subjects relating to aspects of ionizing radiation.

Navy laboratories have been established in several localities to develop methods for the prevention of radiation injury to those who are making a study of the target vessels used in the Bikini bomb tests. At the Naval Medical Research Institute studies are being conducted concerning the biologic effects of radiation on the laboratory animals employed in the tests. In this connection the Bureau of Medicine and Surgery will present an exhibit on "The Medical Aspects of the Development and Utilization of Atomic Energy" at the Centennial Celebration in Atlantic City, June 9-13.

In an effort to provide essential information to medical personnel, the Bureau of Medicine and Surgery is now preparing a manual on radiologic safety for all medical officers (including Reserve officers on active and inactive duty), nurses and Hospital Corps personnel. This will contain the basic information not only on nuclear physics but also on certain medical aspects of atomic energy. Those who show interest and aptitude in this specialized field will be given advanced, personalized instruction.

It is believed that within a few months a faculty of well trained naval medical officers may be assembled for the purpose of giving a combined basic and advanced course in the medical aspects of atomic energy. The date of this course will be announced later.

PLASTIC SURGERY FACILITIES

The Surgeon General of the Navy, Rear Admiral Clifford A. Swanson, has offered all facilities available in plastic surgery at the U. S. Naval Hospital, Houston, Texas, to aid in the reconstruction work of the burned patients of Texas City, following the disaster of April 16. This offer follows an announcement by Dr. I. Daniel Shorell of New York that he was calling for volunteers in the field of plastic surgery to help with the plastic work on the burn victims of that city. There are 350 persons in the hospitals of Texas City who need plastic surgery and many others who suffered disfiguring wounds. Admiral Swanson made this offer to both Dr. Shorell and Mayor J. C. Trahan of Texas City in order that the Navy might assist in this program as it did during the first few hours after the explosion.

VETERANS ADMINISTRATION

DEPENDENTS OF DECEASED VETERANS

The Veterans Administration reports that nearly 879,000 dependents of 557,000 deceased veterans of all wars and peacetime service are receiving compensation and pension checks from the Veterans Administration at the rate of over $32,000,000 a month; 396,000 are dependents of deceased World War II veterans. Of these, all but 3,525 are receiving compensation as the result of service connected death of the veteran; 363,000 are beneficiaries of deceased World War I veterans. Only 96,000 of these receive benefits resulting from service connected deaths. The rest are being compensated in cases of veteran deaths which did not result from service in the armed forces. The rolls also include 78,000 dependents of deceased Spanish-American War veterans, 19,000 from the Civil War, 2,345 from the Indian wars, 47 from the Mexican War and nearly 20,000 dependents of veterans who died in peacetime service. Of the dependents 372,000 are widows, 261,000 are children and 246,000 are parents of deceased veterans.

REORGANIZE NEW YORK CITY CLINIC

The New York Regional Veterans Administration has about completed reconstruction and administrative reorganization of its outpatient clinic at 252 Seventh Avenue, which regional office in March gave 87,200 treatments to 24,533 veterans. All types of illness are treated at the clinic by the staff of eighty full time doctors, seventeen dentists, twelve nurses, two hundred and forty-one technicians, seventy-nine consultants and numerous part time professional and subprofessional personnel in addition to the administrative staff. As of May 24 there were 16,241 requests for examination. Efforts were being made by night work to reduce this backlog so that veterans will no longer have to wait any longer than they would have to wait in a private physician's office. According to the New York *Times* an appointment system therefore has been instituted. Before the facilities were ready many of the men were sent to private physicians, but now only those are sent to private physicians that would suffer hardship if they had to come to the clinic. The potential veteran load for this area is estimated at 964,945 for the New York office and 335,839 for Brooklyn. A clinic will be opened in Brooklyn at 35 Ryerson Street during the summer.

NUMBER OF DISABILITY COMPENSATIONS OR PENSIONS

Living veterans receiving disability compensation or pensions now number 2,328,000. Their benefit checks total about $114,000,000 per month; 1,736,000 are World War II veterans, of whom all but 3,000 have service connected disabilities. The remainder is made up of 432,000 World War I veterans, 116,000 from the Spanish-American War, 99 from the Civil War, 873 from the Indian wars and 43,000 veterans disabled in peacetime service. The bulk of World War II claims, 1,208,000 cases, has been added to the rolls in the twenty months since VJ day. The number of new World War II disability claims filed per month has declined slowly from 70,000 in September 1946 to 50,000 last month. New awards in April totaled 12,638 cases, indicating that some 10,000 previously approved World War II awards were dropped during that month.

PERSONAL

Dr. J. A. Rosenkrantz has been appointed chief, outpatient department, Veterans' Hospital, Bronx, N. Y. He is a graduate of Columbia University College of Physicians and Surgeons, a specialist certified by the American Board of Internal Medicine and in the recent war served as commanding officer of an advance section of a medical laboratory and as chief of the medical service of a station hospital.

Dr. Joseph L. Kubanek, Detroit, has been appointed chief of the neuropsychiatry division at the veterans hospital, Dearborn, Mich. Dr. Kubanek for many years on the staff of the Wayne County General Hospital, has been certified by the American Board of Psychiatry and Neurology.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

DISTRICT OF COLUMBIA

Cancer Clinic for Children.—A new clinic for children with suspected cancer has been opened in Gallinger Municipal Hospital with funds from the National Cancer Institute of the United States Public Health Service. Its services are available to pediatricians throughout the district for examination, tests and diagnosis of children with abnormal growths. It is open every Wednesday at 12:30 p. m. Dr. Roy Hertz, Bethesda, Md., endocrinologist of the National Cancer Institute, is director.

Washington Diabetes Association.—The newly organized affiliate of the American Diabetes Association, organized in Washington for educational and scientific research purposes, consists of two groups: the Clinical Society, made up of qualified practitioners in the Washington metropolitan area or the state or county medical society in which they reside and physicians in military service or governmental departments and research workers in any field of medicine or its allied sciences. Associate members consist of dietitians, laboratory technicians, nurses and social workers. The Lay Society is made up of diabetic patients and their relatives and other laymen interested in the subject. Dr. John A. Reed is president and Dr. J. Ross Veal secretary-treasurer.

GEORGIA

University News.—Jose F. Nonidez, Sc.D., professor of anatomy, Cornell University Medical College, New York, on July 1 will succeed the late Dr. Joseph Krafka as head of the department of microscopic anatomy at the University of Georgia School of Medicine, Augusta.

Cancer Detection Clinic.—The Atlanta Cancer Detection Center has been organized by the Georgia Division, American Cancer Society, in space provided by the Sheffield Clinic, Georgia Baptist Hospital, Atlanta. Patients are seen by appointment only. No treatment is given.

IDAHO

State Medical Meeting at Sun Valley.—The annual session of the Idaho State Medical Association will be held in Sun Valley, June 16-19, at the Challenger Inn under the presidency of Dr. George C. Halley, Twin Falls. The scientific program will be provided by members of the faculty of Harvard Medical School, Boston: Drs. C. Sidney Burwell, internal medicine; Alan R. Moritz, legal medicine and pathology; Edward D. Churchill, surgery; Merrill C. Sosman, radiology; J. Hartwell Harrison, urology. Among the subjects to be reviewed are x-rays in the examination of the gastrointestinal tract; advances in the diagnosis and treatment of liver diseases; nature and treatment of surgical shock; neoplasms of the kidney: their differential diagnosis and treatment; management of high blood pressure; medical investigations of obscure and suspicious deaths in the interest of public safety, and nephrolithiasis: recent advances in diagnosis, treatment and prevention. There will be round table discussion groups for luncheon Monday, Tuesday and Wednesday with one of the guest speakers at each table. The annual banquet will be in the Lodge dining room Tuesday at 8:15 p. m. The Women's Auxiliary will meet June 16-19 also.

ILLINOIS

Five Deaths in Typhoid Epidemic.—The fifth death from typhoid in an epidemic that began early in April in Christian County was reported June 4. Baxter K. Richardson, senior administrative officer of the state board of health, said that he had received reports of 43 cases, all of which have been traced to an ice cream handler in Palmer. The state health department reported that the carrier had sold his business and returned to former employment as a steelworker elsewhere after agreeing to a modified quarantine.

Chicago

Epidemic Keratoconjunctivitis.—The Chicago Medical Society reports that several cases of epidemic keratoconjunctivitis have been reported in the Chicago area. In 1943 this disease swept eastward from the west coast and reached the epidemic stage. All suspected cases should be placed under immediate medical treatment and be reported to the health department.

Nursing Scholarships for High School Girls.—The Chicago Chapter, American Red Cross, will award student nursing scholarships to four senior high school girls of advanced standing who have taken the Red Cross Home Nursing training in their school course. The scholarships will cover all tuitio to the nursing school selected plus a monthly stipend for a period of three years.

Society Elections.—The Chicago Pediatric Society has elected the following officers for 1947-1948: Dr. H. William Elghammer, president; Dr. John L. Reichert, vice president; Dr. Alvah L. Newcomb, secretary, and Dr. Craig D. Butler, treasurer.——At the ninetieth annual meeting of the Chicago Academy of Sciences, May 12, Dr. Nathan Smith Davis was reelected president; William F. Henderson, Ph.D., and Leslie Arey, Ph.D., vice presidents.

Personal.—Dr. Andrew C. Ivy, vice president of the University of Illinois, left June 2 for Nuremberg, Germany, to serve as adviser at the trials of Nazi doctors charged wit crimes of a medical nature, serving as a special consultant t the secretary of war. He will return in three weeks. Dr. Iv has made two previous trips to Nuremberg, having serve as the United States representative on an international commission which investigated Nazi human experiments last Jul and having testified on the ethical principles of medical investigations, studies and experiments conducted by Nazi doctors o trial last January.

INDIANA

One Case of Smallpox at Elkhart.—Smallpox develope in a high school student in Elkhart late in April. Dr. Ivan J Markel, secretary, City Board of Health, reports that no othe case has developed and that the source of infection could not b determined.

Tumor Registry.—The Indiana Cancer Society, in collaboration with the state board of health and the cance committee of the state medical association, is setting up a tumo registry. It will develop a roster of all verified cases of cance which have been hospitalized within a given period. There ar seven hundred and thirty fully classified histories on file now

Dr. Barrett to Head Bureau of Local Health.—Dr Daniel C. Barrett, Bloomington, director, southeastern branc office, Indiana State Board of Health, has been appointe director of the Bureau of Local Health Administration. Dr Barrett, a graduate of Indiana University School of Medicine Bloomington, also holds a Master of Public Health degree fro Johns Hopkins University, Baltimore. He has served as medical director of city, county and district health department in Iowa, Kansas and Indiana, and during the recent war wa with the U. S. Public Health Service.

KENTUCKY

Rural Medical Scholarship Fund Exceeds Goal.—The statewide campaign to raise a rural medical scholarship fund of $100,000 has exceeded its goal by over $50,000. The campaign sponsored by the Kentucky State Medical Association and the University of Louisville School of Medicine ended with a dinner May 8, at which H. Fred Wilkie, chairman of the drive, presided. The campaign, launched last fall, was aimed to aid medical students by lending money for tuition on their pledge that they practice for a while in Kentucky's rural areas. According to the state department of health, unless more young doctors go into rural practice in Kentucky immediately there will be only 481 active practicing physicians in all of rural Kentucky, or 1 doctor to 4,159 people, as compared to 1 for every 1,500 considered necessary for adequate medical care. Besides Mr. Wilkie, Senator Henry Ward, Paducah, has been vice president and Dr. Irvin Abell, Louisville, headed the finance committee. Dr. Carl C. Howard, Glasgow, has been chairman of the fund's board of trustees.

MARYLAND

Society News.—At the semiannual meeting of the Baltimore City Medical Society April 11 Dr. William G. Lennox, assistant professor of neurology, Harvard Medical School, Boston, discussed "The Modern Treatment of Epilepsy."

Hospital Sesquicentennial.—Spring Grove State Hospital, Catonsville, the third oldest hospital for the treatment of the insane in the United States, celebrated its one hundred and fiftieth anniversary May 8 with an all day scientific program. Organized in 1797 for the medical treatment of seamen, it has grown to be a hospital of 2,214 beds.

MICHIGAN

Occupational Therapy Teaching Center.—Wayne University College of Medicine, Detroit, announces the opening of a new teaching center in Grace Hospital for its occupational therapy curriculum. Although the curriculum utilizes the facilities of three of Wayne's colleges and many of Detroit's clinical training facilities, the professional training itself will be offered at the new center. Medical phases of the instruction are to be directed by Dr. Max K. Newman, a psychiatrist at the hospital and a member of the Wayne faculty of medicine.

Personal.—Dr. Adolph T. Rehn, assistant medical superintendent of the State Home and Training School at Lapeer, has been appointed superintendent. A graduate of Wayne University College of Medicine, Detroit, he has been assistant physician and director of the feebleminded at the state hospital at Newberry at various times.——Dr. Fred O. Henker, formerly of the U. S. Public Health Service, has been appointed director of the Michigan Venereal Rapid Treatment Center at Ann Arbor to succeed Dr. Clement A. Smith, who has joined the staff of the University of Michigan Hospital.

Grant for Training Practical Nurses.—Wayne University's College of Nursing has received a grant of $26,400 from the W. K. Kellogg Foundation to finance a three year program in the training of teachers of practical nursing. This is the second major grant the foundation has made this year to the College of Nursing. A grant of $60,000 for the development over a three year period of advanced programs in medical, surgical and public health nursing was reported last January. The purpose of the new program will be to train nurse instructors who will be qualified to develop courses of instruction throughout the state for the training of practical nurses. The plan has been recommended jointly by the Michigan Council on Community Nursing, the Michigan Department of Public Instruction and the National Association for Practical Nurse Education.

NEW HAMPSHIRE

State Medical Meeting at Newcastle.—The annual meeting of the New Hampshire Medical Society will be held at the Hotel Wentworth, Newcastle, June 19-20 under the presidency of Dr. Ralph W. Tuttle, Wolfeboro. Round table conferences will open at 10 o'clock each morning, with general meetings following. Guest speakers include:

Dr. Hart E. Van Riper, New York, Poliomyelitis: Problems and Treatment.
Dr. Harrison L. McLaughlin, New York, Dislocations of the Shoulder.
Dr. Sara M. Jordan, Boston, The Peptic Ulcer Problem.
Dr. Dwight E. Harken, Boston, Surgery of the Heart.
Dr. Yale Kneeland Jr., New York, Antibiotics.
Dr. Harold W. Brown, New York, Indications for Early Surgical Correction of Strabismus.
Dr. John E. Howard, Baltimore, Male Hormone Deficiencies.
Dr. Nicholson J. Eastman, Baltimore, Episiotomy.
Dr. James R. Miller, Hartford, Conn., Internal Public Relations in Medicine.
Dr. Leland S. McKittrick, Boston, Clinical Aspects of the Surgical Gallbladder.

On Thursday night Harry H. Haight (MC), U.S.N., will present a technicolor movie of the Bikini incident. Friday afternoon fifty year membership certificates will be presented to Drs. Charles F. Nutter, Nashua, and Vladimir N. Sikorsky, Salem. An informal banquet will be held Friday at 7 p. m.

NEW YORK

Personal.—Dr. Harry A. Pattison, director of the Potts Memorial Institute, Livingston, N. Y., has been invited to read a paper on "Rehabilitation in the United States" at a joint meeting of the Tuberculosis Society of Scotland and the Tuberculosis Association of England and Wales on July 16. He will also attend the meeting of the National Association for the Prevention of Tuberculosis in London. Dr. Pattison will sail from New York on July 2.

Academy Adds a Section on Microbiology.—At the last meeting of the New York Academy of Medicine the request of a group of experts in the field of microbiology for the organization of the section of microbiology was approved. This, the twelfth section of the academy, will encourage the exchange of information among microbiologists and promote contacts between clinical and laboratory investigators. Dr. Gregory Shwartzman, Mount Sinai Hospital, New York, was elected chairman, and Dr. Harry Most, New York University College of Medicine, New York, secretary.

Tuberculosis in Upstate New York.—Tuberculosis in upstate New York is largely concentrated in Erie, Westchester, Monroe, Nassau, Onondaga, Albany, Oneida and Suffolk counties, which have 53 per cent of the upstate population; however, together they contribute 62 per cent of the total tuberculosis deaths, each having more than 50 per year. Thirty-eight other counties having 27 per cent of the total population contribute only 19 per cent of the total tuberculosis deaths. A study of deaths during 1944-1946 shows that out of each hundred thousand people 32 die of tuberculosis each year in the upstate area. The death rate varies in the fifty-seven counties from 10 in Yates County to 50 in Erie County. Most of the 1,980 deaths each year are among men and women in the most productive period of their lives.

New York City

Medical College Acquires Site for Expansion.—The Long Island College of Medicine, Brooklyn, on May 13 obtained title to a three block tract of land comprising 6 acres bounded by Clarkson, New York and Brooklyn avenues and Lenox Road, which tract is opposite the Kings County Hospital. An expansion program estimated to cost $5,450,000 in the initial phase is under way, and this tract will become a new campus for the medical school. The medical college, founded in 1860 as the teaching department of the Long Island College Hospital, was established in 1930 as an independent and privately operated medical school.

New York Academy of Medicine Awards.—At the Convocation of Fellowship meeting of the academy, April 24, eight Bowen-Brooks Scholarships of $500 each were presented to Drs. William Henry, New York; Joseph F. Hindman, Brooklyn; Martin H. Orens, Bellrose; Maurice S. Raben, Valhalla; Emanuel Lawrence Reichel, New York; Chauncey R. Southworth, New York; Stanley Stellar, Brooklyn, and Joseph R. Wilder, New York, all medical students. The Louis Livingston Seaman Award, given for aid and investigation in bacteriology or sanitary science, $1,000 to Professor James M. Neill, Ph.D., Cornell University Medical College, New York; $500 each to Dr. Arnold W. Pratt, New York Hospital, New York; Dr. Alwin M. Pappenheimer, New York University College of Medicine, New York, and Dr. Samuel J. Prigal, New York. The Edward N. Gibbs Memorial Prize of $1,500 was awarded to Dr. Stanley E. Bradley, assistant professor of medicine, Columbia University College of Physicians and Surgeons, New York.

Training and Research in Ophthalmology.—Extensive research is under way at the Eye Bank for Sight Restoration, Inc., with headquarters at 210 East Sixty-Fourth Street. The principal objectives are the discovery of a method for the preservation of corneal tissue over a longer time than seventy-two hours, improvement of surgical technic of corneal grafting, the use of fibrin as a substitute for sutures, and development of methods for transplanting vitreous. The eye bank has granted seven fellowships for research during the past year and sixteen scholarships for its training course on transplanting corneal tissue. Physicians from other countries who have come here on scholarships or fellowships from the eye bank include Dr. John D. Blum, Geneva, Switzerland; Dr. Walter Kornblueth of the Hebrew University, Jerusalem; Dr. Geminiano de Ocampo, Manila, instructor in eye, ear, nose and throat, Philippine General Hospital; Dr. M. K. Yue, Fukien China; Dr. P. K. Kuo, Shanghai, China, and Major M. M. A. Dubash, Bombay, India.

NORTH CAROLINA

Annual State Meeting at Virginia Beach.—The Medical Society of the State of North Carolina held its annual meeting May 12-14 at Virginia Beach, Va., under the presidency of Dr. William M. Coppridge, Durham. Out of state speakers at the general sessions were:

Dr. R. Franklin Carter, New York, Tumors of the Neck Encountered in General Surgical Practice.
Dr. Ashley W. Oughterson, New York, Strategic Planning for Control of Cancer.
Dr. J. Edwin Wood Jr., Charlottesville, Va., Significance of Renal Sodium Excretion in Congestive Heart Failure.
Dr. Raymond Hussey, Detroit, Human Relations Approach to Occupational Health.

Guest speakers at the sectional meetings Tuesday and Wednesday afternoons also included Dr. Harold W. Brown, New York, and Dr. Harry H. Ware Jr., Richmond, Va.

Professor Hollinshead Goes to Minnesota.—Dr. W. Henry Hollinshead, associate professor of anatomy, Duke University School of Medicine, Durham, has accepted the appointment of professor of anatomy, Mayo Foundation and Graduate School of Medicine, University of Minnesota, Rochester, Minn. He will organize and head a department of anatomy which is being established by the Mayo Clinic and will continue research on the peripheral nervous system and mechanisms in the reflex control of respiration and blood pressure. Dr. Hollinshead is one of the original staff of the Duke University School of Medicine, having been a member of the department of anatomy since 1930. He will assume his new duties July 1.

PENNSYLVANIA

Dr. Essick Honored.—At a testimonial dinner June 5 in Reading the mental hygiene committee of the Council of Social Agencies of Berks County honored Dr. Charles R. Essick, vice president of the board of the Guidance Institute of Berks County. Dr. Essick's interests include recreation for the children of the city, for whom he has donated tracts of land to provide park and playground space. He has promoted the program of the Reading Tuberculosis Association, of which he has been president, and the Guidance Institute, which he helped to establish.

Fifty Year Testimonials.—At the annual meeting of the 10th Councilor District in Pittsburgh May 15 twenty-two veteran physicians were presented with fifty year testimonials: Drs. Harry A. Barnhardt, Charles I. Buvinger, William A. Caven, E. Roy Gardner, Henry M. Hall Jr., Alexander R. Hampsey, Clarence H. Ingram, Edward E. Mayer, William P. McCorkle, Alpheus McKibben, William T. Pyle and William G. Shallcross, all of Pittsburgh; Charles G. Eicher, McKees Rocks; Clarence L. Leydic, Tarentum; John B. Rugh, Pitcairn; Alfred B. Sigmann, Bridgeville; Frederic S. Kellogg, Adrian, Mich.; John R. Owens, North Canton, Ohio; Edward G. Ankney, Pleasant Unity; John A. Boale, Vandergrift; Walter Witherspoon, Derry, and Robert M. Eagleson, New Castle. Dr. Howard K. Petry, Harrisburg, president of the Medical Society of the State of Pennsylvania, presented the testimonials. At a dinner of the Cambria County Medical Society in April six physicians were honored on the completion of fifty years of service in their profession. The six physicians so honored were Drs. Charles J. Hemminger, Somerset; David H. Sangston, Uniontown; Clarence B. Millhoff, Johnstown; Milton A. Noon, Everson; Charles W. Spragg, Waynesburg, and George S. Wallace, Marianna.

Philadelphia

Plans to Expand Two Municipal Hospitals.—The city council has allocated $5,000,000 for increasing the bed capacity and providing modern facilities at Philadelphia's two municipally owned hospitals. As a part of the $20,000,000 program plan, Mayor Bernard Samuel said that 1,000 additional beds would be provided at Philadelphia General Hospital, and a new 650 bed general hospital will be erected at the Philadelphia Hospital for Contagious Diseases. Plans for Philadelphia General Hospital are divided into four stages, permitting the demolition of obsolete structures and the erection of new buildings with minimum interference. A new dormitory for student nurses and interns residence, additions and alterations to the existing receiving ward, an operating building and power plant and a separate building for 600 patients suffering with chronic chest diseases are included in the plans. The 650 bed addition to Philadelphia Hospital for Contagious Diseases will not increase the present 1,050 bed capacity but will allow part of the present hospital structure to be utilized for the new general hospital. Tuberculous patients will be moved to Philadelphia General Hospital.

TEXAS

Texas Medical Center.—The third construction job to be started in the Texas Medical Center, Houston, will get under way within the next two weeks with excavation for the new $3,500,000 Hermann Hospital. The 395 bed hospital will bring the capacity of Hermann Hospital to 695, exclusive of bassinets, as the present institution has 300 beds. The new building will be at the northern edge of the medical center and eastward from the Professional Building now under construction. The latter fourteen story building will provide office space for doctors and dentists teaching and practicing in the center. The Baylor University College of Medicine building is nearing completion and will open its doors to students in September. It is the first completed building in the twenty-five or so proposed for the medical center.

VIRGINIA

Three Counties Unite in Health District.—Effective May 1, Surry County was joined to Sussex, Prince George and Dinwiddie counties, creating the Sussex-Prince George-Dinwiddie-Surry Health District with headquarters at Stony Creek. Dr. Francis J. Clements, Stony Creek, is the health officer.

J. Shelton Horsley Memorial Lecture.—Dr. Edward D. Churchill, the John Holmans professor of surgery at Harvard Medical School, Boston, delivered the first J. Shelton Horsley Memorial Lecture April 22 in Richmond on "Historical Notes on the Management of Wounds of the Thorax." This lectureship was established by Dr. Guy W. Horsley, Richmond, in memory of his father and will be given each spring at the regular meeting of the Richmond Academy of Medicine by medical men in the fields of surgery, physiology and pathology.

Changes in Health Officers.—Dr. Walter R. Johnson, Garrisonville, assumed duties as health officer of the Alleghany-Botetourt health district, with headquarters at Covington, Va., April 1.——Dr. Merle V. Bemis, Center Conway, N. H., has been appointed health officer of the Buchanan-Tazewell health district, with headquarters at Richlands, Va.——Mr. George W. Jones Jr., formerly assistant director, hospital division, Medical College of Virginia, Richmond, has been appointed to the state department of health to assist in the indigent hospitalization program.

WASHINGTON

State Urological Society.—Nineteen urologists met in Seattle April 17 and organized the Washington State Urological Society, which will petition the Washington State Medical Association for recognition as a section under that organization at the fall state meeting. Officers elected were Drs. Frank J. Clancy president, Jack N. Nelson vice president and Harold E. Eggers Jr. secretary-treasurer, all of Seattle. Dr. William L. Ross Jr., Yakima, was designated chairman of the organization committee, which will bring in a proposed constitution and by-laws at the next meeting. The purpose of the new society is purely scientific.

Dr. Allen Inaugurated President of University.—Dr. Raymond B. Allen, acting president of the University of Washington since July 1946, was inaugurated as president at ceremonies last month. Dr. Allen received his Ph.D. degree in neurology at the University of Minnesota, 1934. He was dean of Columbia University College of Physicians and Surgeons, 1934 to 1936, and associate director, New York Post-graduate Medical School and Hospital, Columbia University, 1932 to 1936. From 1930 to 1939 he was dean of Wayne University College of Medicine, Detroit, and from September 1939 to 1943 was executive dean of the Chicago colleges of the University of Illinois; from 1943 to 1946 he was dean of the University of Illinois College of Medicine, Chicago.

WISCONSIN

Dr. Meek Elected to National Academy.—Walter J. Meek, Ph.D., professor of physiology and associate dean of the Medical School of the University of Wisconsin, has been elected to membership in the National Academy of Sciences. From 1942 to 1945, in addition to duties in the department of physiology, he served as acting dean of the medical school in the absence of the dean. His contributions in the field of physiology have been extensive, the heart and vascular system having been the primary areas of his study. In addition, he has served as chairman of the advisory board of the William Beaumont Foundation, Inc.

Course in Care of Infantile Paralysis.—The University of Wisconsin Medical School, Madison, will present an intensive course in care and treatment of infantile paralysis during the week of June 23-28 at the Medical School and State of Wisconsin General Hospital and Wisconsin Orthopedic Hospital for Children in Madison. The course is being given under the auspices of the National Foundation for Infantile Paralysis, Inc., as well as the state organizations. Enrolment will be limited to physicians from communities throughout the state, who will be selected by the local Infantile Paralysis Organizations. The diagnosis of the disease and the immediate care of the patient will be emphasized. Further information may be obtained from Dr. Llewellyn R. Cole, coordinator of graduate medical education, the University of Wisconsin Medical School, 418 North Randall Avenue, Madison 6.

MEXICO

Meningitis Epidemic.—According to the Pan American Sanitary Bureau, 59 cases of epidemic cerebrospinal meningitis were reported in the city of Monterrey, State of Nuevo Leon, from February 15 to March 29. Forty more were reported during the first twenty-three days and 19 in the following three weeks; 12 cases and one death in the city of Saltillo, Coahuila from February 23 to March 16. In San Luis Potosi, 250 miles southward, 23 cases were reported in February and 16 in March.

GENERAL

International Congress of Experimental Cytology.—This society will meet in Stockholm, Sweden, July 10-17. The Swedish organization committee has planned the congress as a series of symposiums dealing with chemical constituents of the cell, submicroscopic structure of the protoplasm (including viruses), nuclear and cytoplasmic interactions, cell metabolism and development, growth and differentiation. Secretaries of the congress are Professor T. Caspersson and Docent H. Hydén, Karolinska Institutet, Institute for Cell Research, Stockholm.

International Spanish Speaking Physicians.—At a recent meeting of the board of directors of the International Spanish Speaking Association of Physicians it was decided to hold a Latin American Congress and a short questionnaire has been sent to its members requesting their opinion on where to hold the congress and in what month and on what subjects they prefer to read papers before the congress. The president and founder of this association is Dr. Jacob M. Gershberg, New York. The general secretary is Dr. William B. P. McDonough, 161 East Eighty-First Street, New York.

Cardiovascular and Respiratory Sounds.—An album of thirteen records, twenty-six sides, designed to reproduce the heart sounds and breath sounds in health and disease has been prepared by Dr. E. H. Stokes, Sydney, Australia, and recorded by Amalgamated Wireless (Asia) Limited. Records reproduce the normal heart sounds as well as the arrhythmias, murmurs and other adventitious sounds encountered in various types of heart disease. Normal and pathologic breath sounds are reproduced in like manner. The records are of the plastic variety and are singularly free from surface noise. The sounds are described in Australian accent.

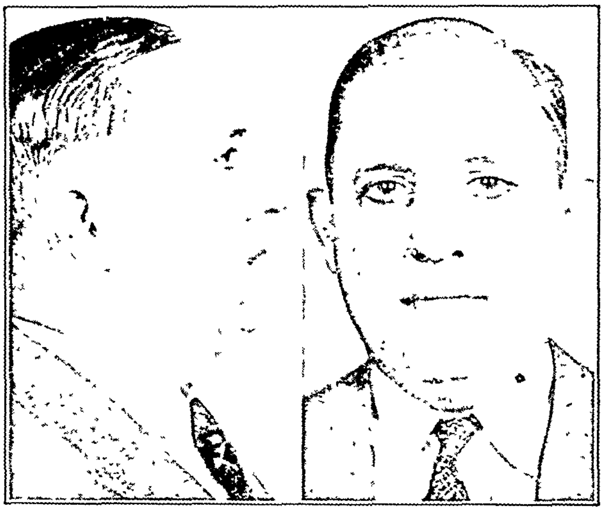
State Directors of Local Health Service.—The first postwar conference of State Directors of Local Health Services took place in Topeka, Kan., April 10-11. In attendance were representatives of twenty-two states having directors of local health services and delegates of other states. The group gave first consideration to the establishment of a basis for a permanent association, explored the possibility of district organization and 'blueprinted channels for more ready and profitable utilization of information on local health practice throughout the states and territories. Officers elected for the current year were Drs. Monroe F. Brown, Tennessee, president; John W. Shackelford, Oklahoma, and Vivian A. Van Volkenburgh, New York, vice presidents, and Mr. Richard F. Boyd, Illinois, secretary.

National Research Council Awards.—The National Research Council has announced the initial five awards under a $100,000 fund established by Merck & Co., Inc., to provide promising young scientists with further research training in the closely allied field of chemistry and biology. The selections made by the council from forty-nine applicants are Joseph Lein, New York, for advanced study at the California Institute of Technology on the specificity of enzymes produced by mutated and non-mutated genes in neurospora; Lorin John Mullins, Palo Alto, Calif., for advanced work at the Naples, Italy, Zoological Station on the experimental modification of permeability phenomena in marine vertebrates and invertebrates; Arthur Beck Pardee, Pasadena, Calif., for research at the University of Wisconsin in general physiology, histology, cytology and related fields as preparation for a career in medical research, and B. Roger Ray, Nampa, Idaho, for work at the Rockefeller Institute for Medical Research, New York, on the determination of movements of salts through certain nonaqueous solutions by means of high speed centrifugation.

Special Society Elections.—At the annual meeting of the American Pediatric Association in Philadelphia, May 21, Dr. William C. Menninger, Topeka, Kan., was named president-elect to succeed Dr. Winfred Overholser, Washington, D. C., who assumed the presidency. Dr. Leo H. Bartemeier, Detroit, was elected secretary and Dr. Howard W. Potter, New York, treasurer.——At the recent meeting of the National Academy of Sciences Dr. Alfred N. Richards, vice president in charge of medical affairs of the University of Pennsylvania School of Medicine, Philadelphia, was elected president. Frederick E. Wright, Ph.D., Carnegie Institution, Washington, was reelected home secretary.——At the meeting of the American Society for Pharmacology and Experimental Therapeutics, Chicago, May 18 to 22, the following officers were elected: Dr. Maurice H. Seevers, department of pharmacology, University of Michigan Medical School, Ann Arbor, Mich., president; Dr. Carl A. Dragstedt, professor of pharmacology, Northwestern University Medical School, Chicago, vice president; Dr. Harvey B. Haag, Medical College of Virginia, Richmond, secretary, and Dr. Ko Kuei Chen, Indianapolis, treasurer.

Meetings of World Health Organization Committees.—Three expert committees of the World Health Organization Interim Commission have held meetings recently, the first in Ottawa, Canada, March 10-21, when the International Committee for the Preparation of the Sixth Decennial Revision of the International Lists of Diseases and Causes of Death convened. Detailed recommendations were made for consideration by the sixth decennial conference, which is scheduled to meet in Paris in March 1948. The Subcommittee for the Revision of the Pilgrimage Clauses of the International Sanitary Conventions met in Alexandria, Egypt, April 16 and made an eight day field inspection of the Suez area, El Tor, Jidda and other points. This committee is formulating recommendations on revision of sanitary convention clauses governing health aspects of pilgrimages. The Expert Committee on Malaria convened in Geneva, Switzerland, April 21, for five days. Recommendations of that committee will be made to the World Health Organization Interim Commission and will be considered by its Committee on Epidemiology and Quarantine when it meets in the fourth session in Geneva on August 30.

Warning—Stock Swindler Among Physicians.—Hobart M. Prosser, alias Harry Moore, is being sought by the Federal Bureau of Investigation on a warrant issued for his arrest June 6, 1946 at Louisville, Ky. After inveigling physicians to buy Canadian stocks, he manages to regain possession of the stock and disappears. He is 64 years old, 5 feet 6½ inches tall, weighs 160 pounds, has brown eyes and hair and is medium stout. He has a brown mole on the back of his left hand, an irregular scar on his upper lip and another on his left temple. He has had a colostomy. His former residence is Oak Park, Ill. Any person having information which may assist in locating Prosser is requested to notify immediately the director of the Federal Bureau of Investigation, U. S. Department of Justice, Washington, D. C., or the nearest special agent in charge of the division of the Federal Bureau of Investigation.



Hobart M. Prosser, alias Harry Moore.

Marriages

Emory Arthur Rittenhouse, McKeesport, Pa., to Miss Ellen A. Cheves of Atlanta at Fort Myer, Va., recently.

Richard Morris Moore, Des Moines, to Miss Polly Van Zile of Evanston, Ill., in Bloomington, Ill., Dec. 21, 1946.

Walter Stauffer Price, Washington, D. C., to Miss Patricia Jean Darling of Lowell, Mass., recently.

Dorn C. Pittman of Fairmont, N. C., to Miss Betty Mitchell of Winston-Salem February 22.

Roscoe F. Morton, Dumas, Ark., to Miss Mary Jane Tolliver of Carthage, Mo., February 22.

Milton L. Kroungold to Miss Betty Roseman, both of Philadelphia, Sept. 18, 1946.

Alexander Leavitt to Miss Beatrice Schiffman, both of Brooklyn, in February.

Deaths

Eben James Carey ⊕ dean and professor of anatomy at Marquette University School of Medicine in Milwaukee, died June 5, aged 57, of acute infectious hepatitis. Born in Chicago July 31, 1889, Dr. Carey attended high school in Los Angeles and took his premedical work and two years of medical studies at the University of California in Berkeley-San Francisco. He graduated from Rush Medical College Chicago, in 1925, and served an internship at the Presbyterian Hospital in that city. He received the bachelor of science, master of science and doctor of science degrees from Creighton University in Omaha, where he taught for six years before coming to Marquette University in 1920. While at Marquette he was dean of medical students from 1921 to 1928, medical director of the Free Dispensary from 1924 to 1928 and chief of staff of the University Hospital from 1926 to 1928. He was commissioned a first lieutenant in the Reserve Officers' Training Corps and later became a lieutenant colonel in the National Guard of Wisconsin. He was a fellow of the American Association for the Advancement of Science and the New York Academy of Medicine, a member of the Milwaukee Academy of Medicine, serving as its president in 1939 and 1940, Chicago Institute of Medicine, the American Association of Anatomists and a former vice president of the Association of American Medical Colleges. The Radiological Society of North America awarded him a gold medal in 1933 in recognition of his x-ray study of bone growth. He was chairman of the program committee of the council on scientific work of the State Medical Society of Wisconsin, which in 1938 presented him with the Council Award. In 1931 he was chairman of the scientific exhibition of the Interstate Postgraduate Assembly in Milwaukee. During the Century of Progress in Chicago in 1933 and 1934, Dr. Carey was director in charge of medical exhibits. He was a member of the advisory committee on medical exhibits at the Texas Centennial in Dallas in 1935 and 1936, the Golden Gate International Exposition in 1939, and since 1931 had been director of medical science exhibits at the Museum of Science and Industry in Chicago. He was a member of the Council on Physical Medicine and of the advisory committee of the Scientific Exhibit of the American Medical Association. He was awarded the silver medal of the Association for an exhibit on the dynamics of origin, structure and repair of bone at the convention in Minneapolis in 1928, a citation of merit at the convention in Portland in 1929 for his exhibit illustrating a continuation of the experimental studies on bone growth, citation of merit in Detroit in 1930 and Philadelphia in 1931, in 1937 at Atlantic City, the silver medal for an exhibit on intrinsic wave mechanics of the nervous and muscular systems; and in 1942 in Atlantic City he received a gold medal for his exhibit on experimental ameboid motion of motor end plates. Dr. Carey was the author of "Studies in Anatomy" published in 1924 and of many scientific articles. More recently he gave much time to research on poliomyelitis. He was especially devoted to the advancement of medical education and to the education of the public in health.

Eben James Carey, M.D., 1889-1947

Arthur D. Knott ⊕ Camilla, Ga.; born in Belton, Texas, June 27, 1876; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; formerly professor of preventive medicine and hygiene at the Medical College of Virginia, Richmond; health officer of Mitchell County; for many years health officer of Wood County in Parkersburg, W. Va.; at one time health commissioner of Accomack County in Virginia; past president of the West Virginia Public Health Association and the Ashley County (Ark.) Medical Society; fellow and life member of the American Public Health Association; served during World War I; received his degree of doctor of public health from Johns Hopkins University in Baltimore; died in the Archbold Memorial Hospital in Thomasville, March 19, aged 70, of coronary occlusion.

George Hale Ryder, Quincy, Mass.; Harvard Medical School, Boston, 1919; member of the American Medical Association and the New England Ophthalmological Society; fellow of the American College of Surgeons; for many years affiliated with the Massachusetts Eye and Ear Infirmary in Boston and consulting surgeon at the Norfolk County Hospital in Braintree; consulting surgeon at Quincy City Hospital; specialist certified by the American Board of Ophthalmology; formerly on the faculty of Tufts College Medical School and Harvard Medical School; died March 12, aged 72, of coronary thrombosis.

Howard David MacFarland ⊕ Utica, N. Y.; Baltimore Medical College, 1910; member of the American Urological Association; past president and for many years treasurer of the Oneida County Medical Society; member of the staff of the Faxton Hospital, where he had been president for many years; consulting physician, St. Elizabeth Hospital, Utica Memorial Hospital and the Broadacres Sanatorium; formerly health officer of Rome, where he had been on the staff of the Rome Hospital; died March 6, aged 59, of skull fracture received when he fell from a third story window.

John Morgan Settle, Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1929; member of the American Medical Association; fellow of the American College of Surgeons; associate in obstetrics and gynecology at the Medical College of the State of South Carolina; specialist certified by the American Board of Obstetrics and Gynecology; on the staffs of St. Francis Xavier Infirmary and the Baker Memorial Sanatorium; died in the Roper Hospital March 25, aged 41, as a result of burns received in December when he fell asleep while smoking.

George A. Anderson, Springville, Utah; Jefferson Medical College of Philadelphia, 1909; formerly mayor of Springville; on the staff of the Utah Valley Hospital in Provo; died March 28, aged 65, of heart disease.

Henry Watson Armistead, Indianapolis; Meharry Medical College, Nashville, 1894; died in the City Hospital March 25, aged 79, of arteriosclerosis.

Henry Grady Banister, Ila, Ga.; Emory University School of Medicine, Atlanta, 1916; member of the American Medical Association; served during World War I; died in Clearwater Beach, Fla., March 2, aged 55, of carcinoma of the lungs.

Everette Erwin Butler, Louisville, Ky.; University of Louisville Medical Department, 1918; member of the American Medical Association; on the staff of the Norton Memorial Infirmary; died in Vero Beach, Fla., March 23, aged 54, of injuries received in an automobile accident.

William Howard Cantrell, Oklahoma City; University of Oklahoma School of Medicine, Oklahoma City, 1940; member of the American Medical Association; served during World War II; died March 9, aged 32, of acute dilatation of the heart.

Salvatore Castallo ⊕ Providence, R. I.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1896; died March 18, aged 75, of cardiovascular disease.

Thomas E. Chapman, St. Paul, Va ; Kentucky University Medical Department, Louisville, 1904; served during World War I; died in Norton March 17, aged 69, of cerebral hemorrhage.

Charles Matthew Coe, St. Louis; College of Physicians and Surgeons of Chicago, 1883; died March 21, aged 88, of chronic myocarditis.

John George Dickert ⊕ Englewood, N. J.; Long Island College Hospital, Brooklyn, 1893; also a graduate in pharmacy; an Affiliate Fellow of the American Medical Association; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; served as consulting surgeon, Brooklyn Eye and Ear Hospital and the Bethany Deaconess Hospital, Brooklyn, where he died March 13, aged 75, of gangrenous cholecystitis.

Thomas Roche Donovan ⊕ Fitchburg, Mass.; Tufts College Medical School, Boston, 1909; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; on the staff of the Burbank Hospital; died March 30, aged 64, of bronchopneumonia and arteriosclerotic heart disease.

Paul Harold Ellis ⊕ Omaha; John A. Creighton Medical College, Omaha, 1899; past president of the Omaha-Douglas Counties Medical Society; died in Los Angeles March 12, aged 70, of coronary thrombosis and carcinoma of the ileum.

Edward Stanley Emery Jr., ⊕ Boston; Harvard Medical School, Boston, 1920; instructor in medicine at his alma mater; specialist certified by the American Board of Internal Medicine; member of the American Gastro-Enterological Association and the American Society for Clinical Investigation; on the staff of the Peter Bent Brigham Hospital, where he died March 15, aged 52, of coronary occlusion.

Henry Wilson Fancher ⊕ Thompsonville, Conn.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1925; interned at the West Baltimore General Hospital in Baltimore and the New Britain (Conn.) General Hospital; served during World War I; on the staffs of the Springfield and Wesson hospitals in Springfield, Mass.; died March 19, aged 47, of coronary thrombosis.

John Lee Farmer ⊕ Passed Assistant Surgeon, Lieutenant Commander, U. S. Navy, retired, San Diego, Calif.; Baylor University College of Medicine, Dallas, 1918; entered the U. S. Navy on Jan. 5, 1921; retired June 1, 1932 for incapacity resulting from an incident of the service; since 1942 anesthetist at the San Diego County General Hospital; died in the U. S. Naval Hospital January 10, aged 52, of cerebral hemorrhage.

Jasper Jewett Garmany, New York; Bellevue Hospital Medical College, New York, 1882; formerly clinical professor of surgery at the New York University College of Medicine; died March 26, aged 88, of heart disease.

Harrison Milton Gibson ⊕ Moline, Ill.; Rush Medical College, Chicago, 1920; president of the staff of the Moline Public Hospital, where he died March 16, aged 52, of cerebral edema caused by cerebral thrombosis.

Robert Hall Glover, Philadelphia; University of the City of New York Medical Department, New York, 1894; for many years a medical missionary; since 1943 home director emeritus of the China Inland Mission; died March 23, aged 75.

Emil Hahn ⊕ Cincinnati; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; served during World War I; on the staff of the Jewish Hospital, where he died March 8, aged 66, of carcinoma of the esophagus.

Louis Joseph Halloin, Luxemburg, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; died March 2, aged 79, of injuries received when struck by an automobile as he was crossing the street.

John Alexander Hunter, Cleveland; University of Wooster Medical Department, Cleveland, 1912; member of the American Medical Association and the Cleveland Academy of Medicine; an examiner for a draft board during World War II; on the staff of the Polyclinic Hospital; died March 25, aged 64, of coronary disease.

George Rheems Irwin ⊕ Bridgeport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; school physician; member of the police commission; Reading railroad physician; died in Norristown, Pa., March 16, aged 78, of injuries received when struck by an automobile as he was crossing the street.

Thomas Zadock Johnson, Walnut Ridge, Ark.; Memphis (Tenn.) Hospital Medical College, 1902; member of the American Medical Association; past president of the Lawrence County Medical Society; died March 1, aged 75, of cerebral hemorrhage.

Charles William Karraker ⊕ Louisville, Ky.; Louisville and Hospital Medical College, 1908; past president of the board of the Kentucky Baptist Hospital, where he died March 14, aged 65, of coronary occlusion.

Jacob Meek Lanning ⊕ Miami, Okla.; Memphis (Tenn.) Hospital Medical College, 1902; died March 7, aged 72.

Daniel Henry Lawler, Hammond, Ind.; University of Maryland School of Medicine, Baltimore, 1912; member of the American Medical Association; served during World War I; director of health of the public schools; died March 15, aged 59, of coronary embolism.

Raymond Vincent Lawrence ⊕ Rochester, N. Y.; University of Buffalo School of Medicine, 1913; served during World War I; member of the Rochester Academy of Medicine; on the staff of St. Mary's Hospital; died March 12, aged 57, of myocarditis.

John Joseph McDermott ⊕ St. Joseph, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1914; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; affiliated with the Mercy Hospital in Benton Harbor and St. Joseph Sanitarium; died in the Wesley Memorial Hospital, Chicago, March 19, aged 59, of myocardial infarction.

John Roy McDowell ⊕ Lakewood, Ohio; Western Reserve University Medical Department, Cleveland, 1905; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America; served overseas during World War I; on the staff of the Lakewood Hospital, where he died March 10, aged 68, of coronary occlusion.

Edward C. Nast, Douglas, Wyo.; Denver and Gross College of Medicine, 1906; died in the Converse County Memorial Hospital March 24, aged 64, of myocarditis.

John Southworth Niles Sr., ⊕ Carbondale, Pa.; Jefferson Medical College of Philadelphia, 1891; fellow of the American College of Surgeons; joined the staff of the Emergency Hospital, which later became the Carbondale General Hospital, where he resigned as chief of staff in 1944, a position he had held for many years; died March 21, aged 84, of coronary occlusion.

Michael A. O'Hare, Cincinnati; Miami Medical College, Cincinnati, 1905; member of the American Medical Association; died March 12, aged 68, of hypertensive heart disease.

Hiram Olsan ⊕ Rochester, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1909; died March 18, aged 63, of coronary occlusion.

Hovhanness Kevork Peltekian, Baltimore; Baltimore Medical College, 1893; served during the Spanish-American War and World War I; major, medical reserve corps, not on active duty; member of the Association of Military Surgeons of the United States; on the staff of the Maryland General Hospital, where he died March 8, aged 75, of coronary occlusion

J. Edward Richmond, Weirton, W. Va.; Louisville (Ky.) Medical College, 1905; member of the American Medical Association; past president of the Hancock County Medical Society; served as health officer of Hollidays Cove, physician for the state police and on the staffs of the Ohio Valley Hospital and the Gill Memorial Hospital in Steubenville; died March 13, aged 64, of coronary disease.

Albert F. Schmeling, Columbus, Wis.; Milwaukee Medical College, 1898; died in St. Mary's Hospital February 2, aged 79, of cerebral thrombosis and cerebral arteriosclerosis.

William Lord Smith, New York; Harvard Medical School, Boston, 1892; an associate of the American Museum of Natural History in New York; fellow of the Royal Geographical Society; died in the Brattleboro Retreat in Brattleboro, Vt., recently aged 83, of bronchopneumonia and cerebral arteriosclerosis.

Charles R. Vance, Bristol, Tenn.; University of Virginia Department of Medicine, Charlottesville, 1891; member of the Medical Society of Virginia and the American Medical Association; veteran of the Spanish-American War; died February 26, aged 79, of coronary thrombosis and cerebral embolus.

Morley S. Vaughn, Carleton, Mich.; Detroit College of Medicine, 1912; interned at the Jackson City Hospital in Jackson, where he served as chief physician and surgeon at the State Prison of Southern Michigan; affiliated with the Monroe (Mich.) Hospital, where he died March 15, aged 59, of chronic nephritis.

Theodore Luther Vosseler ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1905; associate professor of anatomy at his alm mater; fellow of the American College of Surgeons; surgeon, Carson C. Peck Memorial Hospital; consultant, Brooklyn Eye and Ear Hospital; died March 20, aged 72, of coronary thrombosis.

Grant Bixler Weaver, Lancaster, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1906; served overseas during World War I; served as medical inspector for the U. S. Veterans Bureau; on the visiting staff of the St. Joseph's Hospital; died March 10, aged 67, of heart disease.

AUSTRALIA

(From Our Regular Correspondent)

April 1, 1947.

Free Medical Services Still a Long Way Off

The minister of health and social services in the commonwealth government said in Sydney recently that the free medical services envisaged under the referendum were from ten to fifteen years distant. Plans at the moment were almost nonexistent. The commonwealth had to face shortages of materials, equipment and personnel as well as the difficulty of agreeing on doctors' payments. The free medical services scheme called for an institute for training doctors, nurses and administrators; pathologic laboratories; x-ray, maternity, gynecologic and tuberculosis hospitals; research institutes; the manufacture, sale and distribution of medical equipment, and provision of specialist services. A vast increase in the demand for better hospitals would call for hospital administrators of a high caliber.

Director of Medical Research for Queensland

Dr. Ian M. Mackerras, one of Australia's leading entomologists, has been selected from eleven overseas and two Australian applicants as director of the new Queensland Institute of Medical Research. The purpose of the institute is to carry out research into any factor, social or economic, affecting the health of the public. A veteran of both world wars, Dr. Mackerras was responsible for much of the army's malaria control and associated entomologic and field parasitologic work. His investigations on scrub thyphus, anopheline vectors of malaria and transmission of dengue fever made possible the control of these diseases, which played such an important part in the Southwest Pacific campaign. In 1944 Dr. Mackerras was sent by the army director general of medical services to England and America to study research work being performed in the chief malaria research laboratories in those countries. He later visited Panama, West Africa and Canada to make additional studies.

An Australian Tuberculosis Association

At the fifth session of the Australian Medical Congress in Adelaide, South Australia, in 1937 tuberculosis was given special consideration. Emphasis was laid on governmental responsibility in tuberculosis control. Not that the obligations of the medical practitioner in the care of the individual patient were minimized, but his efforts were shown to be only partially effective unless allied to active and whole hearted departmental cooperation.

The idea that one tuberculosis association should be brought into being to cover the whole commonwealth originated in South Australia when the South Australian Tuberculosis Association adopted its new constitution in 1943. Among the objects was a determination to foster the formation of an Australian National Tuberculosis Association. A draft constitution for an all Australian association was submitted to a committee convened for the purpose in New South Wales. It was agreed that the Australian Tuberculosis Association should be formed and should consist of six branches, one from each state. By the agency of such a body, it was thought that propaganda could be directed to state and federal governments and that this propaganda should work for increased efforts to eradicate the disease and for the securing of adequate economic relief for sufferers and their dependents. It was also considered that steps should be taken by means of leaflets, films and radio and press publicity to form an enlightened public opinion so strong and held by such numbers of people that governments in office would be forced to take notice, since the opinion of the people who elect them to office is the only kind of opinion which influences politicians. A third advantage of the projected association would be the encouragement of the study of the disease in all its forms and relationships. Much of the setup for the association has been culled from the National Association for the Prevention of Tuberculosis in England and from the constitutions of associations in Canada and the United States. The new association will not be concerned with treatment. It will help to create conditions in which treatment can be undertaken with the greatest possible benefit to the individual patient and to the community. The ultimate aim is the increase of preventive treatment and the decrease of curative treatment until a stage is reached at which the latter will seldom need to be used.

Prevention of Silicosis with Aluminum

Although there is no evidence that the inhalation of aluminum powder affects established silicosis, the method is justified as a prophylactic under some circumstances. This was the general summary of a report by Dr. W. E. George of the Bureau of Medical Inspection, Broken Hill, New South Wales, after a visit to Canada and the United States to study the use of different types of aluminum powder in the prevention and treatment of silicosis. Dr. George reported that there was sufficient experimental evidence to justify the use of aluminum powder as a prophylactic, under strict supervision, in some circumstances. If, in an industry, the employer found that silica dust was still being inhaled by his employees after the reduction of the dust hazard to its economically practicable minimum, or if the men employed showed a susceptibility to silicosis or evidence of the progression of preexisting silicosis, they should receive aluminum inhalation treatment on a voluntary basis, provided they showed no evidence of active tuberculosis. In addition to receiving the aluminum, such men should be removed from exposure to silica dust.

Dr. George also considered that a course of prophylactic aluminum treatment could be given to men who have been exposed to dangerous quantities of silica dust within the past two years (provided tuberculosis is not present), regardless of lack of hazard in their present occupation. Also if it should become necessary to expose men to known hazardous concentrations of silica-containing dust which, because of the nature of the process, cannot be satisfactorily controlled by engineering methods, these men should receive aluminum powder by inhalation during the period they are exposed to such hazard.

However, emphasis is laid on the fact that constant supervision of the aluminum powder treatment and the recording of careful clinical observations, including periodic lung x-ray examination, are necessary if the true value of the process is eventually to be assessed. All treatment with aluminum powder should be on a voluntary basis, after its experimental nature has been explained to those whom it is proposed to treat. There is no justification at present for applying aluminum treatment to all employed in an industry unless there is definite evidence that silicosis is being produced in that industry. Aluminum inhalation should not be used indiscriminately. The best method of prevention of the development of silicosis remains the elimination of the dust hazard by controlling the liberation of dust into the atmosphere at its point of origin, and under no circumstances should the use of aluminum be permitted to lead to any relaxation in the control of silica hazards by competent engineering and medical supervision.

These conclusions seem consistent with those reached in the joint Council reports on the prevention and treatment of silicosis (The Journal, April 27, 1946, p. 1223).

VACCINATION AGAINST SMALLPOX

To the Editor:—In view of the nationwide problem of vaccination against smallpox which now faces this country, it is significant that a number of simple, yet very important, details are not common knowledge among the public and the medical profession.

In private practice the matter of dressings is a constant source of discussion between physician and patient or parent of the child to be vaccinated. Considerable conservation of time and avoidance of misunderstanding can be effected by placing a plain band-aid over the insert immediately after vaccination. In my experience no harm can come from such a type of dressing. This may be removed the following day, and further dressings need not be used. However, with the appearance of the vesicle (about the fourth day) daily application of 3 per cent picric acid solution in medicated ("rubbing") alcohol produces a hard, resistant vesicle. To quote the original source of this information (Ratner, Bret: Allergy, Anaphylaxis and Immunotherapy, Basic Principles and Practice, Baltimore, Williams & Wilkins Company, 1943, p. 271), "Much or all of the difficulty of the subsequent care of the vaccination can be prevented by daily application to the vesicle of a 3 per cent picric acid solution in medicated alcohol. This produces a hard, resistant vesicle. The child can be bathed throughout the period of vesiculation and pustulation. Secondary infection is minimized, no protection is needed, scarring is lessened because of the smaller degree of pustulation and finally itching is reduced. There is no interference in any way with successful vaccination. I have used this method for the past twenty years with complete satisfaction, after having read about its use by a medical army officer in some journal which reference I cannot recall. Schamberg and Kolmer (1911) also report on this method, advising the use of 4 per cent picric acid solution in 70 per cent alcohol." I have observed the formation of a hard, resistant vesicle within twelve to twenty-four hours after several applications of 3 per cent solution in medicated ("rubbing") alcohol, and the parents have unanimously praised the procedure.

Since occasional instances of postvaccinal tetanus have been reported, every effort should be made to immunize infants and children against the disease (tetanus) preceding vaccination. It is therefore pertinent that the alum precipitated toxoid can be given at intervals of three to four weeks (instead of three months) without interfering with the development of adequate immunity (to be published later). Hence the present nationwide urge toward vaccination against smallpox can be utilized to immunize against tetanus (alone or against diphtheria simultaneously by the use of diphtheria-tetanus toxoid). Obviously, the absence of immunity against tetanus should not deter the physician from vaccinating, particularly if the picric acid solution (as described) is employed.

The selection and preparation of the site for vaccination justify comment. The use of the deltoid region is safer than the lower extremity (less likelihood of infection). With the multiple pressure technic, using a very small insert, supplemented by the use of the picric acid solution in alcohol, the problem of disfiguring scars may be dismissed. The best technic is described by Ratner (see previous reference): "The skin of the upper arm in the region of the depression formed by the insertion of the deltoid muscle should be gently but thoroughly cleansed with acetone on sterile gauze or cotton and wiped or allowed to dry a few seconds. Acetone is suggested as a cleansing agent rather than alcohol for the following reasons: 1. It is a more efficient cleanser. 2. It is cheaper. 3. It is not denatured with substances which may possibly affect the vaccination result. 4. It evaporates more rapidly. 5. Approximately 200 vaccinations performed after the use of acetone and alcohol on alternate subjects resulted in more successful vaccinations with acetone than with alcohol."

Most patients or parents find it difficult to understand the course of vaccination (no immunity, partial immunity, complete immunity and unsuccessful). Verbal descriptions leave them more confused than enlightened. Consequently a colored description of the various types of take is of value. A good example may be found in Holt and McIntosh's textbook of pediatrics. I have used this for instruction in my office and have found it invaluable. It would be very helpful to have an office form describing the various types of local reaction so that parents could determine whether or not the vaccinations have pursued a proper course.

A word of caution is indicated concerning constitutional reactions to vaccination. The appearance of fever and associated complaints with the appearance of the pustule may or may not be caused by the vaccination. I can recall several instances in which constitutional complaints at the time of the pustulation were caused by other diseases (e. g. influenza bacillus meningitis, membranous tonsillitis).

It is commonly believed (at least by the public) that failure of repeated attempts at vaccination indicates immunity. Obviously this belief is an error. Sir William Osler could not be vaccinated successfully but developed smallpox following clinical exposure (see Harvey Cushing's Life of Osler).

Ralph Spaeth, M.D., Chicago.

EOSINOPHILIC GRANULOMA OF BONE

To the Editor:—In The Journal, April 26, there appeared an editorial comment on eosinophilic granuloma of bone. The statement is made "Neither have any visceral lesions been described, a curious feature inviting close study."

I wish to call attention to "Eosinophilic Granuloma of Bone—Report of a Case with Multiple Lesions of Bone and Pulmonary Infiltration" (*Arch. Int. Med.* **79**:176 [Feb.] 1947) by Albert Weinstein, Herbert C. Francis and Bertram F. Sprofkin. In this case are described lesions in the lungs which were best explained by the eosinophilic granulomatous lesion which was proved to be the nature of the bone lesions. These pulmonary changes disappeared under x-ray therapy as did the bone lesions. We feel very strongly that this is a true instance, and therefore the initially reported example, of a visceral lesion as part of the clinical picture of eosinophilic granuloma of bone.

The possible relationship of Letterer-Siwe's disease, Hand-Schüller-Christian syndrome and eosinophilic granuloma were emphasized in our report by tabulating the data presented in the review by Mallory (Medical Progress: Pathology: Disease of Bone, *New England J. Med.* **227**:995 [Dec. 10] 1942).

Albert Weinstein, M.D., Nashville, Tenn.

To the Editor:—I wish to draw your attention to the case report by Dr. Eulyss R. Troxler and myself in the *Annals of Internal Medicine* (**25**:960 [Dec.] 1946). This is with reference to the editorial comment on eosinophilic granuloma of bone in The Journal, April 26, page 1284.

Our case demonstrates the skeletal, cerebral and pulmonary manifestations of generalized xanthomatosis. Eosinophilic granuloma represents only one phase of this generalized disease. We believe that wherever there is reticuloendothelium there can be lipoid granulomatosis. Thus the clinical symptoms produced depend on the tissues involved and the degree of involvement. Many names have been given to these various manifestations, such as eosinophilic granuloma of bone, Hand-Schüller-Christian syndrome and Letterer-Siwe disease.

David Niemetz, M.D., Beverly Hills, Calif.

POSTGRADUATE COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

Compiled by the Council on Medical Education and Hospitals for Period July 1, 1947 to Jan. 15, 1948

Medical schools, hospitals, state medical societies and other medical educational institutions and organizations are providing the Council with a growing body of information on courses designed primarily to meet the needs of returning medical officers. These have been incorporated into the lists on these pages. They are not specifically designated for veterans, since most if not all of them may also be open to interested civilian physicians. Furthermore, all courses listed which were not designed primarily for physician veterans are also open to qualified returning medical officers.

Note that each course is listed only once, without cross indexing, so that in some instances a prospective student should look under more than one heading for a desired course.

Table of Contents

Subject	Page	Subject	Page	Subject	Page
Allergy	626	Chemistry	628	Fractures	630

Postgraduate Courses for Practicing Physicians—July 1, 1947 to Jan. 15, 1948

Institution	Title of Course	Schedule of Course	Registration Fee and/or Tuition
	ALLERGY		
University of California Medical School, San Francisco 22	Orientation Course in Clinical Allergy	5 days, full time, July 7-11, 1947	$40.00
Cook County Graduate School of Medicine, 427 S. Honore St., Chicago	Allergy	1 month, full time, 1st of every month	200.00
	Personal Course in Allergy	6 months, 1st of month when plans are available	125.00
	Allergy and Related Conditions	10 weeks, part time, October 8, 1947	125.00
University of Illinois College of Medicine, 1853 W. Polk St., Chicago At Chicago Professional Colleges	Allergy	1 year, full time, September 29, 1947	Residents 300.00 Nonresidents 600.00
Wayne University College of Medicine, 1516 St. Antoine St., Detroit	Allergy Clinic and Conference	1 morning a week for 1 qtr., July 1947	per qtr. 25.00
	Allergy Clinic and Conference	1 morning a week for 1 qtr., October 1947	per qtr. 25.00
At Receiving Hospital	Allergy Clinic and Conference	3 months, Tuesday mornings, July 1, 1947	25.00
American College of Allergists, 401 La Salle Medical Bldg., Minneapolis 2 At University of Cincinnati College of Medicine, Cincinnati, Ohio	Post Graduate Instructional Course in Allergy	1 week, November 3-8, 1947	100.00
Long Island College of Medicine and Medical Society County of Kings, 1313 Bedford Ave., Brooklyn 16 At Beth El Hospital	Allergy	8 sessions, once a week, October 9, 1947	20.00
At Kings County Hospital	Allergy	8 sessions, once a week, October 7, 1947	20.00
Columbia University College of Physicians and Surgeons, 630 W. 168th St., New York 32 At Mount Sinai Hospital	Allergy	2 weeks, part time, October 20-29, 1947	40.00
At Roosevelt Hospital	Recent Advances in Allergy	1 week, full time, November 10-15, 1947	40.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York	Allergy	2 months, part time, arranged	50.00
New York Post-Graduate Medical School, 303 E. 20th St., New York 3	Allergy	3 weeks, full time, November 5-25, 1947	200.00
	Allergy	8 sessions, part time, January 9-February 27, 1948	25.00
American College of Allergists, 401 LaSalle Medical Bldg., Minneapolis At Cincinnati, Ohio	Intensive Fall Graduate Instructional Course in Allergy	1 week, November 3-8, 1947	100.00
Graham Thomas Clinic, 201 W. Franklin St., Richmond 20, Va.	Fellowship in Allergy	1 year, in selected cases 6 months, July 1, 1947	None
	ANATOMY		
Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis, Ind. At St. Elizabeth Hospital, Lafayette, Ind.	*Post graduate Instruction in Anatomy*	2 hours per week, Monday of each week	per week 15.00
University of Maryland School of Medicine, Lombard and Greene Sts., Baltimore	General Anatomy, Review Course	Arranged, part or full time	Varies
	Surgical Anatomy	15 weeks, full time, January 1948	150.00
Wayne University College of Medicine, 1516 St. Antoine St., Detroit	Surgical Anatomy	Every Tuesday afternoon for 1 qtr., October 1947	per qtr. 20.00
University of Minnesota Medical School, Minneapolis 14 At Center for Continuation Study	Anatomy (Dissection)	2½ months, July 1-September 15, 1947	Arranged
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E. 106th St., New York	Applied Anatomy for the Anesthetist	125 hours, arranged	275.00
	Applied Anatomy for the General Surgeon	250 hours, arranged	375.00
	Applied Anatomy for the Otolaryngologist	1 month, full time, arranged	275.00
	Anatomy of the Thorax	100 hours, arranged	150.00
	Anatomy of the Urogenital System	130 hours, arranged	300.00
	Anatomy of the Abdomen	100 hours, arranged	150.00
	Anatomy for the Orthopedic Surgeon	100 laboratory hours, arranged	150.00

University of Kansas School of Medicine, 39th St. and Rainbow Blvd., Kansas City 3	Refresher Course in Anesthesiology	3 days, September 9-11, 1947	15.00
Columbia University College of Physicians and Surgeons, 630 W. 168th St, New York 32 At: Mount Sinai Hospital	Anesthesia Diagnostic and Therapeutic Nerve Blocking	5 weeks, part time, October 21-November 21, 1947	50.00
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E 106th St, New York	Clinical Anesthesiology	3 months, full time, arranged	200.00
New York Polyclinic Medical School and Hospital, 341-353 W. 50th St, New York	Anesthesia	3 months, October 1, 1947-January 2, 1948	300.00
New York Post-Graduate Medical School, 303 E 20th St, New York 3	Anesthesia	Arranged, full time Arranged, starting after September 15, 1947	125.00
New York University College of Medicine, 477 First Ave., New York 16 At: Bellevue Hospital	Anesthesiology	24 weeks, full time, Fall 1947	400.00
	Regional Anesthesia	2 weeks, full time, September 2-13, 1947	150.00
	Regional Anesthesia	2 weeks, full time, January 5-24, 1948	150.00
Duke University School of Medicine, Durham, North Carolina	Anesthesia	3 or 6 weeks, full time, arranged	per mo. 50.00
	ARTHRITIS		
Long Island College of Medicine and Medical Society County of Kings, 1313 Bedford Ave, Brooklyn 16, New York At: Jewish Hospital	Arthritis	8 sessions, once a week, October 8, 1947	20.00
New York Post-Graduate Medical School, 303 E 20th St., New York 3	Arthritis and Allied Rheumatic Disorders	5 days, full time, November 10-14, 1947	65.00
	Arthritis and Allied Rheumatic Disorders	8 sessions, part time, January 6-February 24, 1948	45.00
New York University College of Medicine, 477 First Ave, New York 16 At: Bellevue Hospital	Arthritis and Rheumatic Disorders	6 weeks, part time, September 29, 1947	100.00
	BACTERIOLOGY		
Wayne University College of Medicine, 1516 St Antoine St, Detroit	Newer Bactericidal Agents	1 qtr, 1 afternoon a week, July 1947	10.00
	Parasitology	1 qtr., 1 morning a week, July 1947	20.00
	Parasitology	1 qtr., part time, October 1947	Not given
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E 106th St, New York	Parasitology	6 weeks, half time, arranged	75.00
	Immunology	6 weeks, half time, arranged	50.00
	Bacteriology	3 months, half time, arranged	100.00
New York University College of Medicine, 477 First Ave, New York 16	Bacteriology	Not given, part time Fall 1947	Vets. 50.00 Non Vets 60.00
University of North Carolina School of Medicine, Chapel Hill	Bacteriology and Immunology	Not given, arranged	25.00
Duke University School of Medicine, Durham, North Carolina	Bacteriology and Parasitology	3 months or longer, full time, arranged	per mo. 50.00
	BASIC SCIENCES		
University of California Medical School, San Francisco 22	Training Course in the Basic Sciences[1]	To be announced	To be announced
George Washington University School of Medicine, 1335 H St, N W., Washington 5, D C	Basic Sciences for Physicians	8 months, part time, October 1, 1947-May 30, 1948	175.00
	Basic Sciences for Surgeons	8 months, part time, October 1, 1947-May 30, 1948	175.00
University of Illinois College of Medicine, 912 S Wood St, Chicago	Basic Science	9 months, October 1, 1947	600.00
Indiana University School of Medicine, 1040 W Michigan St, Indianapolis	Basic Science	6 weeks, July 7, 1947	Not given
University of Minnesota Medical School, Minneapolis 14 At Center for Continuation Study	Basic Sciences and Their Clinical Application	10 months, full time, September 28, 1947-June 14, 1948	Arranged
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E 106th St, New York	Basic Medical Sciences	9 months, full time, October 1947	Other 600.00 Surgery 800.00
University of Oklahoma School of Medicine, 800 Northeast Thirteenth St, Oklahoma City	Post Internship Educational Program in Basic Sciences	12 weeks, September 2-November 22, 1947	None
	Post Internship Educational Program in Basic Sciences	12 weeks, December 2, 1947-March 1948	None
Baylor University College of Medicine, 509 Lincoln Ave, Houston, Tex	Residency Training Program	6 months, full time, July 1-December 15, 1947	300.00
University of Wisconsin Medical School, 418 N Randall Ave, Madison 6, Wis	The Basic Sciences	Arranged	sem 145.00
Marquette University School of Medicine, 561 N Fifteenth St, Milwaukee 3	Basic Sciences	6 months, September 1947-February 1948	150.00
	BIOCHEMISTRY		
New York University College of Medicine, 477 First Ave, New York 16	Biochemistry	Part time course Fall 1947	Vets 65.00 Non Vets. 75.00
University of North Carolina School of Medicine, Chapel Hill, North Carolina	Biochemistry	Not given, arranged	25.00
Duke University School of Medicine, Durham, North Carolina	Biochemistry	3 months or longer, full time, arranged	per mo 50.00
	CARDIOVASCULAR DISEASES		
University of Southern California School of Medicine, 1200 N State St, Los Angeles 33 At Los Angeles County Hospital	Cardiology and Vascular Disease (Course 732)	12 months, full time, September 15, 1947-September 15, 1948	1,000.00
	Cardiology (Course 733)	12 weeks, part time, September 15, 1947	50.00

	Continuous Case Seminar[17] (29 seminars)	Once a week, July 3, 1947 January 15, 1948	87 00
Wayne University College of Medicine, 1516 St Antoine St, Detroit	Orthopsychiatry and Pediatrics	1 qtr, part time, July 1947	Not given
	Orthopsychiatry and Pediatrics	1 qtr, part time, October 1947	Not given
	Clinical Neurology	1 qtr, part time, July 1947	Not given
	Clinical Neurology	1 qtr, part time, October 1947	Not given
	Clinical Psychiatry Seminar	1 qtr, part time, July 1947	Not given
	Clinical Psychology Seminar	1 qtr, part time, October 1947	Not given
	Neuropathology	1 qtr, part time, October 1947	Not given
	Psychology—Infant and Child	1 qtr, part time, July 1947	Not given
	Psychology—Infant and Child	1 qtr, part time, October 1947	Not given
University of Minnesota Medical School Minneapolis 14	Psychosomatic Medicine	2 weeks, arranged	Arranged
Long Island College of Medicine and Medical Society County of Kings, 1313 Bedford Ave Brooklyn 16 At Jewish Sanitarium and Hospital for Chronic Diseases	Clinical Neurology and Neuropathology	8 sessions, once a week, October 3, 1947	20 00
At Jewish Hospital	Child Psychiatry	10 sessions, once a week, October 7, 1947	20 00
American Institute for Psychoanalysis, 266 West End Ave, New York 23	Theory of Neurosis	15 weeks, September 1947	30 00
	Seminar on Dreams[18]	10 weeks, February 1948	20 00
	The Analytic Process[18]	15 weeks, September 1947	30 00
	Introductory Lectures on Psychoanalytic Technique	5 sessions, September 1947	10 00
	Continuous Case Seminar[18]	10 sessions, September 1947	20 00
	Neuroses and Psychoses	15 sessions, September 1947	15 00
	Readings and Psychoanalysis, Part II Reading in Freud	20 sessions, September 1947	40 00
At New School for Social Research	Introduction to the Rorschach Method of Personality Diagnosis	10 lectures, 5 seminars, September 1947	17 50
	Literary Figures in the Light of Modern Psychoanalysis	15 weeks, February 1948	20 00

---

1 Special contract to War Department
2 Specialists only
3 Stipends up to a maximum of $250 00 per month are available if certain qualifications can be met
4 Half fee to physicians in service
5 Followed by 12 months in hospital administrative internship
6 Training given in various institutions throughout country Applicant must make his own arrangement with institution
7 Stipend paid on per diem basis
8 In each teaching district—covering the state in 2 years
9 Pre-requisite—Course 730
10 Evening seminars to be announced during course
11 Fellows and Jr candidates
12 Including dinners and luncheons
13 Write for schedule to Committee on Graduate Education, 230 State St Harrisburg, Pa
14 Includes meals
15 Free to physicians on active duty at Cook County Psychopathic Hospital
16 Full time employees of the Illinois Department of Public Welfare pay no fee
17 Restricted to physician candidates of the Topeka Institute for Psychoanalysis
18 Candidates in training only

(To be concluded next week)

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, June 7, page 556.

BOARDS OF MEDICAL EXAMINERS

Alabama: Montgomery, June 24-26. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

Arizona: * *Examination.* Phoenix, July 1-2. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

California: *Written.* San Francisco, July 7-10. *Oral.* San Francisco, July 19-20. *Oral Clinical Examination for Foreign Medical Graduates.* San Francisco, June 21. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Colorado: * Denver, July 18. Final date for filing application is June 15. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

Connecticut: *Examination.* Hartford, July 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, July 8. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, July 8-10. *Endorsement.* Dover, July 15. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

Florida: * *Examination.* Jacksonville, June 24-25. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

Georgia: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Hawaii: *Examination.* Honolulu, July 8-11. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, July 14-16. Sec., Bureau of Occupational Licenses, Dr. S. M. Poindexter, Eastman Bldg., Boise.

Illinois: Chicago, June 24-26. Sec., Mr. Philip M. Harman, Supt. of Registration, State House, Springfield

Indiana: *Examination.* Indianapolis, June 17-19. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 416 K. of P. Bldg., Indianapolis.

Kansas: *Endorsement.* Kansas City, June 26. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

Kentucky: *Examination.* Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maine: Augusta, July 1-2. Sec., Board of Registration in Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Medical Examination.* Baltimore, June 17-20. Sec., Dr. E. H. Kloman, 1215 Cathedral St., Baltimore.

Massachusetts: *Examination.* Boston, July 8-11. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

Michigan: * Semi-Annual meeting, Lansing, June 24. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

Minnesota: * *Examination.* Minneapolis, June 17-19. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, June 23-24. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

Montana: Helena, Oct. 6-8. Sec., Dr. Otto G. Klein, 302 N. Main St., Helena.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

New Hampshire: *Examination.* Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord

New Jersey: *Examination.* Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, June 23-26. Sec., Dr. Jacob L. Lochner Jr., State Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, June 24. *Examination.* Raleigh, June 23-26. Acting Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Ohio: *Examination.* Columbus, June 17-20. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon: * *Examination.* Portland, July 23-25. Applications must be on file on or before July 9. Sec., Miss Lorienne M. Conlee, 608 Failing Bldg., Portland.

Rhode Island: * *Examination.* Providence, June 19-20. Chief, Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: Columbia, June 23-25. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * Pierre, July 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

Utah: Examinations are held in June of every year. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: Richmond, June 18-21. Sec., Dr. K. D. Graves, 306 Medical Arts Bldg., 30½ Franklin Rd., Roanoke.

West Virginia: *Examination.* Charleston, June 30, July 1-2. Commissioner, Public Health Council, Dr. Newman H. Dyer, State Capitol, Charleston 5.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: June 17. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

Iowa: Des Moines, July 8. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Compensability of Injury from Mercury Bichloride Poisoning.—The claimant filed a petition for disability compensation alleged to be due to him for injuries resulting from mercury bichloride poisoning contracted during the course of his employment. From an award in favor of the claimant, the defendant employer and insurer appealed to the Supreme Court of Florida.

Of the 9th, 10th and 11th of August 1943 claimant was directed by his employer to wash the interior of a building with a solution of bichloride of mercury. He had been a painter for many years but had had no previous experience with, or knowledge of the dangerous nature of, the mercury solution. The only warning given was not to get the solution in his mouth. The building in which he worked was not ventilated, the weather was hot and mosquito bites were plentiful. Conditions were favorable for poisonous fumes to penetrate his body and blood stream. On the 20th claimant complained to the foreman on the job and requested relief under the workmen's compensation law but the foreman rejected the claim because claimant had suffered no accident. In December following, claimant's teeth became loose, his gums became red and swollen, his fingers and finger nails turned brown. From all appearances he was a very sick man. Soon thereafter the doctors diagnosed his ailment as nephritis or "Bright's disease," caused by the absorption of bichloride of mercury.

The question which claimed the most attention, said the court, was whether or not the injury was caused by an accident as contemplated by the workmen's compensation act. The point was made that claimant did not use the poisonous solution through an accident. This is not important. Neither, continued the court, will recovery be precluded because reputable medical testimony was introduced to show that the ill effects would have appeared sooner if the injury had been caused by the mercury poisoning. The commission found that the workman was enclosed without ventilation in hot weather, causing the pores of his skin to open; mosquitoes punctured his skin. He was a strong and well man before then. The period of time for the poison to react would naturally depend somewhat on the degree of physical resistance of the individual, as well as on the peculiar conditions surrounding the exposure.

It was urged that the element of time, place and cause must be clearly proved, but evidence was abundantly clear, said the court, that the cause of claimant's ailment was mercury poisoning, absorbed in the Link Trainer building on August 9th, 10th and 11th, 1943. It is objected that claimant was unable to identify some event which preceded the injury. The event, said the court, was the sudden entry of the poisonous fumes into his body. The injury followed. The victim had no way to recognize the event. None of the five senses will detect the fumes of mercury poison. In fact, the court pointed out, the damage to the blood stream and kidneys is painless, the victim's first knowledge being when and after the injury has been done.

We are satisfied, concluded the court, that this judgment rests on an inference of liability which is sustained by the facts, namely: Claimant was well immediately preceding the 9th, 10th and 11th of August. He was sick soon after. During those three days he was exposed to a highly dangerous solution which undoubtedly would cause the kind of illness of which he soon became a sufferer. The evidence showed a natural sequence of events based on facts from which liability could be inferred. The judgment in favor of the claimant was affirmed.—*Mechan v. Crowder, 28 So. (2d) 435 (Fla., 1946).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

73:257-390 (March) 1947

*Pathogenesis of Passive Rh Isosensitization in Newborn (Erythroblastosis Fetalis). Ruth R. Darrow and Josephine Chapin.—p. 257.
Pathogenesis of Mongolism. T. H. Ingalls.—p. 279.
Blood Pressure of Normal Girls from 3 to 16 Years of Age. M. Elizabeth Downing.—p. 293.
*Alexander's Rabbit Serum in Treatment of Influenzal Meningitis: Evaluation of Its Use in Conjunction with Sulfonamide Compounds. K. H. Beck and F. R. Janney.—p. 317.
*Xanthoma Tuberosum, Aortic Stenosis, Coronary Sclerosis and Angina Pectoris: Report of Case in Boy 13 Years of Age. C. D. Cook, H. L. Smith, C. W. Giesen and G. L. Berdez.—p. 326.
Pyloric Stenosis in Twins: Review of Literature and Report of Case. J. H. Laubscher and A. M. Smith.—p. 334.

Pathogenesis of Passive Rh Isosensitization.—According to Darrow and Chapin, analysis of cases of erythroblastosis fetalis not only corroborates Levine's theory of isoimmunization but supports also the concept of sensitization of the anaphylactic type. These two states, both based on antigen-antibody relationships, appear to be present to varying extents but are not necessarily parallel in occurrence or severity. This produces the extreme variety of symptoms. The passive isoimmune reaction is presumed to take place between the specifically modified (maternal) globulin and the baby's Rh-positive erythrocytes, resulting in their destruction. The reversed, passive isosensitization reaction, on the other hand, would be expected to occur within the tissue cells, principally those of the liver, between the specific sensitizing antibody and the Rh antigen freed by the destruction of the Rh-positive erythrocytes. This intracellular reaction produces injury to the cell, causing histamine and other cellular constituents having toxic effects to be released into the circulation. These substances, in turn, have a damaging effect on susceptible tissues elsewhere in the body.

Alexander's Rabbit Serum for Influenzal Meningitis.—Beck and Janney review observations on patients with influenzal meningitis who were admitted to the Milwaukee Children's Hospital from January 1939 to April 1946, which is the span of time since Alexander's serum has been available and sulfonamide compounds have been given in massive dosages. Previous to this time only 3 of 66 patients with proved influenzal meningitis had survived. Of 45 patients treated during the period when Alexander's serum was available, 24 died and 21 recovered, but 9 of 24 fatalities occurred within the first twenty-seven hours after hospitalization and thus cannot be considered in judging the efficacy of immune rabbit serum in combination with sulfonamide drugs. Of 22 patients who were treated adequately according to Alexander's standards, 19 recovered and 3 died. Of 9 patients treated with sulfonamide drugs and without serum therapy, 2 lived and 7 died. Diagnosis of influenzal meningitis must be made early in order to combat it effectively with rabbit serum and sulfonamide drugs. The sulfonamides must be given in high concentrations and by intravenous or subcutaneous routes. Serum should be preceded by intravenous fluids so that the free floating type-specific carbohydrate of the organism is eliminated from the blood stream and the dehydration alleviated. Alexander's anti-influenzal rabbit serum (administered according to her recommendations) combined with sulfonamide drugs is 85 per cent efficient in cases in which therapy is instituted before the patient is moribund. To date it is the only efficient method for treating meningitis due to Hemophilus influenzae type B.

Xanthoma Tuberosum and Heart Disease.—Cook and his co-workers report the occurrence of xanthoma tuberosum, a typical history of angina pectoris and significant changes in the electrocardiogram in a boy aged 13 years. A review of the literature revealed 20 cases of xanthoma tuberosum with definite or probable cardiac involvement among patients 23 years of age or less at the time the cardiac lesion developed. In 3 of these cases angina pectoris was present. The cardiac lesions in the cases were due to xanthomatous infiltration of the aortic valve and coronary arteries. This hypothesis is substantiated by necropsy in similar cases.

*Studies on Malignant Hepatitis. G. Alsted.—p. 257.
Diagnosis of Acute Respiratory Tract Infections. J. E. Ziegler Jr., E. C. Curnen, G. S. Mirick and F. L. Horsfall Jr.—p. 268.
Changing Concept of Myeloma of Bone. E. Aegerter and R. Robbins.—p. 282.
*Disseminated Calcification of Pancreas: Subacute and Chronic Pancreatitis. C. W. Wirts Jr. and W. J. Snape.—p. 290.
*Experiences with Penicillin and Dicumarol in Treatment of Subacute Bacterial Endocarditis. C. J. Thill and O. O. Meyer.—p. 300.
*Treatment of Acute Diphtheria and Chronic Carrier State with Penicillin. L. Weinstein.—p. 308.
Effects of Blockade of Autonomic Ganglia in Man with Tetraethylammonium: Preliminary Observations on Its Clinical Application. R. H. Lyons, G. K. Moe, Rosalie B. Neligh and others.—p. 315.
Insensitivity to Epinephrine in Patient with Functioning Tumor of Adrenal Medulla. R. L. Mayock and E. Rose.—p. 324.
Increased Reactivity Caused by Adrenalin. E. E. Cameron.—p. 331.
Thiamine Circulation Time. A. Ruskin and G. M. Decherd Jr.—p. 337.
Electrocardiographic Changes Caused by Hyperventilation. D. Scherf and M. Schlachman.—p. 342.
Injectional Treatment of Internal Hemorrhoids. R. Turell.—p. 350.
Complications of Mumps. J. Humphries.—p. 354.
Further Report on Use of Bismuth Sodium Tartrate Intravenously in Treatment of 203 Additional Patients with Tularemia. W. W. Jackson.—p. 358.
Flea versus Rat Control in Human Plague. J. E. Gordon and P. T. Knies.—p. 362.

Malignant Hepatitis.—Alsted says that in Denmark acute hepatitis has run a course parallel to that in the rest of the world. During the last four years the disease has been from seven to eight times as frequent as it was in the prewar period. In 1944 and 1945 a considerable number of patients developed a malignant form of hepatitis. This form occurs chiefly in women over 45 years of age and has a fatality rate of 50 per cent. Most frequently its duration is from four to nine months, but both a much more acute and a more protracted course may be observed. The clinical features are jaundice, frequent febrile attacks of pain and symptoms of portal stasis. As to prognosis, the result of Takata's test is important, whereas the remaining liver function tests are of only secondary value. The lesions are characterized by destruction of the liver tissue and in the more chronic cases by the development of a cicatrized connective tissue. The etiology is obscure. The disease differs from acute infectious hepatitis both etiologically and clinically. The treatment has until now been entirely symptomatic.

Disseminated Calcification of Pancreas.—Wirts and Snape direct attention to the least frequently recognized form of pancreatic lithiasis, known variously as disseminated calcification of the pancreas, pancreatitis petrificans and diffuse parenchymal calcification of the pancreas. They add 2 cases to those existing in the literature. The patients complain chiefly of abdominal pain, which is most frequently present in the epigastrium, going through to the back, but which may also radiate to the right or left hypochondriac regions, the pelvis or either shoulder. The possibility of disseminated calcification of the pancreas should be considered in any patient with a long history of upper abdominal pain. Diagnosis is made on (1) a plane film of the abdomen including that area between the first and fourth lumbar vertebrae, (2) stool examination for total fat and creatorrhea and (3) the pancreatic function test. Recognition of this disease may prevent the needless removal of a gallbladder, appendix or kidney. The clinician should always be on guard to rule out disease of the pancreas when deep seated pain in the epigastrium is associated with mental symptoms. Remaining alert to the possibility of the existence of disseminated calcification of the pancreas is probably the most important single factor in its recognition.

Penicillin and Dicumarol in Bacterial Endocarditis.—Of the 22 patients with subacute bacterial endocarditis reviewed by Thill and Meyer, 13 received both penicillin and dicumarol, and 9 were given only penicillin. Treatment with penicillin alone or combined with dicumarol should be persistent for a minimum of six weeks. This prolonged therapy has given decidedly better results than anything previously employed. Although their results favor combined therapy, the authors remain skeptical that anticoagulant therapy offers advantages. Anticoagulant therapy carries with it grave hazards.

Penicillin for Acute Diphtheria and the Chronic Carrier.—Weinstein reports the effect of penicillin on the clinical course and bacterial flora of the nose and throat in acute cases of diphtheria and on the value of the drug in the chronic diphtheria carrier state. Penicillin has no effect on the clinical course of diphtheria. Its use does not eliminate the necessity of administering adequate amounts of antitoxin. Penicillin reduces the duration of both the convalescent and chronic diphtheria carrier states. A dose of at least 120,000 and preferably 240,000 units of penicillin daily for twelve days is recommended for the treatment of acute diphtheria. A minimum of 240,000 units of penicillin a day for twelve days is suggested for the treatment of the chronic diphtheria carrier state.

American Journal of Medicine, New York

2:229-326 (March) 1947

*Streptomycin Treatment of Urinary Tract Infections, with Special Reference to Use of Alkali. H. W. Harris, R. Murray, T. F. Paine, L. Kilham and M. Finland.—p. 229.
Dienestrol: Another Synthetic Estrogen of Clinical Value. Stella H. Sikkema and E. L. Sevringhaus.—p. 251.
Bacillus Pyocyaneus Infections: Review, Report of Cases and Discussion of Newer Therapy, Including Streptomycin. M. M. Stanley.—p. 253.
Rheumatic Heart Disease in Adult. C. Eggleston.—p. 278.
Treatment of Acute Rheumatic Fever and Acute Rheumatic Heart Disease. L. M. Taran.—p. 285.
Permanent Heart Block Following German Measles. D. Goldfinger, W. Schreiber and P. H. Wosika.—p. 320.

Streptomycin with Alkali in Urinary Infections.—Harris and his associates report the effects of streptomycin in 21 cases of protracted urinary tract infections in which other treatments had either failed or seemed inadvisable. The results obtained suggest that the maintenance of an alkaline reaction of the urine throughout the period of streptomycin therapy increases the efficacy of the streptomycin and reduces the likelihood of the development of streptomycin fastness in the infecting organisms.

Recognition and Significance of Bacteriogenic Gas in Soft Tissues. R. L. Nichols and C. L. Hinkel.—p. 245.

Radiation in Cancer of Eyelid.—The survey presented by Hunt is based on 100 patients selected from 134 seen from 1930 to 1946. Carcinoma of the eyelid is a disease of the elder age group, three fourths of the patients being past 60 years of age. Men are slightly more susceptible than women. Four fifths of the lesions are located along the lower lid or about the inner canthus. Basal cell carcinomas represent three fourths of the neoplasms of the eyelid, and these lesions usually show slow growth. Squamous cell carcinoma of the eyelid, although not common, is a more serious lesion, shows greater local invasion and frequently metastasizes to the parotid or submaxillary glands. Cancer of the eyelid can be as effectively controlled by fractionated roentgen therapy as by surface radium. Careful fulguration is the treatment of choice in the removal of benign moles and papillomas. Surgical ablation of large elevated carcinomas of the eyelid prior to roentgen therapy permits more effective treatment of their base with less mass irradiation of the eyeball and other adjacent nondiseased tissues by both primary and scattered rays. Four of the hundred cases reviewed have ended fatally from cancer of the eyelid during the past fifteen years. Therapeutic failures result from advanced and inaccessible disease, impairment of the tumor bed by prior inadequate therapy, insufficient or uneven dosage, incomplete marginal coverage of lesion, and inadequate follow-up of patients. Superficial roentgen therapy is effective in eradication of cancer of the eyelid with maximal preservation of the uninvolved tissues and with minimal injury to the eye when properly protected by an eyeshield.

Cancer of Tongue.—Sharp and Spickerman present a flexible plan for the eradication of the primary lesion as well as of metastatic cervical involvement in cancer of the tongue. The incidence of lingual carcinoma can be drastically reduced by early recognition and treatment of precancerous lesions. The relation between the site of the primary lesion, the etiology and the degree of malignancy is pointed out. Definite diagnosis of the character of a lesion is possible only on the basis of biopsy and pathologic examination. No ill effects from biopsy were observed in this series. Through medication with penicillin and the *sulfonamide* drug infection of the primary lesion and resultant dissemination of cancerous cells have largely been eliminated. The primary lesion is treated exclusively by irradiation, roentgen therapy being combined with subsequent implantation of radium needles. By using a short target-skin distance, the daily dose has been increased while the total dose has been considerably lowered; thus, the course of roentgen treatments has been reduced to ten or twelve days. For interstitial radium therapy platinum needles have been employed almost exclusively. In the *treatment of metastatic cervical nodes, preoperative* roentgen therapy is combined with subsequent radical neck dissection. When surgery is contraindicated, administration of a larger dose of x-rays is immediately followed by implantation of radium needles. An unselected, consecutive series of 81 cases is reviewed. The described course of treatments led to five year cures in 31.3 per cent of all cases.

Pulmonary Complications of Dorsal Sympathectomy.—Pendergrass and Allbritten review the anatomy and surgical procedure of dorsal sympathectomy. Extrapleural hemothorax, pneumothorax, pleural *effusion*, atelectasis and mediastinal emphysema are the most frequent complications of dorsal sympathectomy. Extrapleural hemothorax is the most serious. Aspiration should be carried out early. Six cases are reviewed. Routine x-ray examinations of the chest should be made within a few days after dorsal sympathectomy.

Tissue Culture in Malignant Tumors.—Grace maintains that tumor cells can be more readily identified by tissue culture than by section. Malignant cells can proliferate from a single cell. This does not take place in normal tissue. This fact may point the way to earlier diagnosis. Increase in activity of tumor cell growth is related to the degree of malignancy. The author has graded tumors into four classes, according to their degree of malignancy. Tissue culture methods have been used to differentiate nodules of Hodgkin's disease from other lymphomas. This procedure should be universally used in the difficult diagnosis of Hodgkin's disease. Tumors with differentiated cells have less tendency to metastasis than those with undifferentiated cells. High activity of cells in tissue culture gives warning of danger.

Streptomycin Therapy for Bacteria.—Pulaski and Amspacher summarize experiences in U. S. Army hospitals with streptomycin therapy in bacteremias due to gram-negative bacilli and gram-positive cocci. The majority of patients received 1 Gm. or more of streptomycin in divided, intramuscular doses, and treatment was continued for an average period of fourteen days. Twenty-two of 24 patients recovered and 2 died. Beneficial results attributable to streptomycin was noted in 18 of the 22 who recovered, while in 4 others the streptomycin was of questionable value. One patient died shortly after the initial dose of streptomycin was given. The other death was of a patient with rapidly progressive fulminating staphylococcic pyemia. Death occurred on the tenth day of therapy. Necropsy confirmed widespread abscess formation and also revealed an acute ulcerative endocarditis. In the 18 cases in which administration of streptomycin was considered beneficial, best results were obtained when the suppurating lesion was amenable to and had the benefit of surgical drainage. Streptomycin therapy in bacteremia can be expected to be successful if the organisms are susceptible in vitro, if the dosage is adequate, if the interval between doses provides bacteriostatic blood levels and the duration of treatment is long enough, if surgical drainage of the primary focus is prompt and exact and if due consideration is given to management of the patient as a whole.

Twenty Day Intensive Therapy with Mapharsen and Bismuth.—Cormia and Blauner review observations in 500 cases of syphilis treated with moderate daily doses of mapharsen over a twenty day period. Mapharsen was given daily for twenty days in a unit dosage of 1 mg. per kilogram of body weight daily with the individual daily dose limited to a maximum of 75 mg. Bismuth subsalicylate in a unit dosage of 0.2 Gm. was administered concurrently at intervals of three days, with a total of eight injections in a period of twenty-two days. The prescribed treatment was completed in 476, or over 95 per cent, of the 500 patients. Types of reactions encountered in the 24 patients in whom the treatment had to be terminated were cerebral irritation, jaundice, toxic erythema, agranulocytosis, severe fever, hemorrhagic encephalitis and persistent albuminuria. Reactions of sufficient severity to interrupt therapy were encountered in 190 patients. BAL, or 2,3-dimercaptopropanol, was administered to 18 patients in 2 cc. ampules by intramuscular injection. The small number of patients treated and the variable plan of therapy do not permit the drawing of definite conclusions regarding the effectiveness of BAL.

Streptomycin in Miliary Tuberculosis.—Baggenstoss and his co-workers present clinical, roentgenologic and pathologic observations in 5 cases of *miliary* tuberculosis treated with streptomycin. Evidence of regression and healing of the miliary tubercles in the lungs was observed roentgenologically in 4 cases, ophthalmoscopically in the choroid layer of the eye in 2 cases and histologically in the lungs and liver in 4 cases and in the spleen in 3 cases. The development of widespread tuberculous meningitis apparently was inhibited in 1 case and was either prevented or cured in 2 other cases. There was renal tubular damage in 1 case, but outside of that there was no microscopic evidence that streptomycin produces toxic effects. The observations on the 5 cases offer further evidence of the efficacy of streptomycin in tuberculosis and offer some hope for the effective treatment of two hitherto consistently fatal forms of the disease.

Functional Behavior of Thyroid Nodules.—The histologic picture of nodules of 6 patients with nodular goiter examined by Puppel and his co-workers showed wide variations. The nodules of patients with toxic nodular and toxic diffuse goiter were of the hyperplasia-involution type. All nodules showed a decreased function when compared with the paranodular thyroid tissues. The nodules of patients with nontoxic nodular goiter, toxic nodular goiter, toxic diffuse goiter and so-called fetal adenoma appeared functionally autonomous. They showed less avidity for administered radio iodine, and also much less thyroxine and diiodotyrosine was made by them than by the surrounding thyroid tissue. The diffuse goitrous tissue of 2 patients with nontoxic diffuse colloid goiter showed great avidity for iodine, but its ability to produce thyroxine and diiodotyrosine did not appear greatly increased. The diffuse hyperplastic tissue of a patient with toxic diffuse goiter showed the greatest avidity for iodine and the greatest ability to produce thyroxine and diiodotyrosine. The diffuse paranodular thyroid tissue of 3 patients with nontoxic nodular goiter showed many of the microscopic characteristics of diffuse colloid goiter. It acted biochemically to a greater extent like the tissue of nontoxic diffuse colloid goiter, which indicates that during thyroidectomy it is this tissue which should be left behind to protect the patient against further decrease in the function of the thyroid gland. Iodine should perhaps be given postoperatively to help restore the remaining tissue. The paranodular thyroid tissue of a patient with toxic nodular goiter acted biochemically to a greater extent like the diffuse hyperplastic tissue of toxic diffuse goiter, which suggested that this tissue should be more adequately resected to decrease the incidence of persistence or pseudorecurrence of symptoms.

Radioactive Sodium in Study of Peripheral Vascular Disease.—Smith and Quimby point out that the use of radioactive isotopes as "tracers" is a new method for obtaining information of the status of the peripheral circulation. Radioactive sodium, introduced into a vein, is rapidly carried throughout all the blood vessels and then passes through the capillary walls into the extravascular fluid. The arrival of the material at an extremity and the nature of its build-up there to equilibrium between intravascular and extravascular fluid can be followed with a Geiger-Müller counter. Curves plotted from these data give information regarding arterial blood supply to the extremity. By correlating this with clinical findings, conclusions can be reached regarding the degree of main or collateral circulation. Estimates can be made of the degree of pathologic change in main or peripheral vascular disease. Cases are presented which indicate the manner in which the curves are used to determine when sufficient collateral circulation exists to warrant local conservative therapy. Similar studies at different levels of the leg have given valuable accurate information as to the site for amputation at which healing is to be expected. This has resulted in more amputations being done below the knee. Observations on patients with essential hypertension indicate that this test can be used to select cases which will or will not respond to thoracolumbar sympathectomy.

Eosinophilic Granulomas of Skin.—According to Weidman the term "eosinophilic granuloma of the skin" was first used in 1937 by Nanta and Gadrat. The disease is not an entity but a histologic syndrome. In view of the frequent plaquelike involvement of the face, it must be taken into account in the differential diagnosis of apparent sarcoid, leukemia, erythema elevatum diutinum and possibly lupus erythematosus. It is not possible to formulate diagnostic formulas or prognoses to cover all cases of this disease. As cutaneous manifestations appear in Loeffler's syndrome in the form of persistent erythema multiforme, it is in order (1) to determine whether sections of skin in this syndrome exhibit the features of eosinophilic granuloma and (2) to take note of the role of Loeffler's syndrome in dermatology. Eosinophilic granuloma of bone does not appear to be related to eosinophilic granuloma of the skin, but the demonstration of fat in cutaneous lesions opens the way for further inquiry through the avenue of Letterer-Siwe disease. In line with the ideas of Sulzberger concerning histamine and allergy, the thesis is offered that the eosinophilic features are but additive to well known dermatologic entities such as erythema multiforme and Hodgkin's disease and that the eosinophilogenic factors may be responsible for obscuring and/or modifying the typical features of such entities.

Granulomatous Hodgkin's Disease with Extreme Eosinophilia.—According to Dobes and Weidman, granulomatous lesions in Hodgkin's disease are relatively rare in the skin. They develop tardily and incompletely compared with those in the lymphadenoid tissues. It appears that in the initial stages the tissue reaction in the skin is far more acute in type than that in the lymph nodes. In the reported case the extreme polymorphonuclear neutrophil reaction was particularly significant. The fibrosis and the development of Sternberg-Reed cells are so seldom exhibited in the skin that the dermatopathologist is denied this assistance in diagnosis in a way that is not the case for the general pathologist. Lymph nodes are far more promising leads toward histologic diagnosis than the skin. The extraordinary eosinophilia in the reported case may or may not be significant for an interrelationship with eosinophilic granuloma. It remains to be demonstrated whether the scope of Letterer-Siwe disease is sufficiently broad genetically to include Hodgkin's disease, but the demonstration of fat in a lymph node of this patient may be significant.

Dermatitis from Glass Fabrics.—Schwartz calls attention to outbreaks of dermatitis from women's suits and children's coats in which the lining was made of Fiberglass, which mechanically irritated the skin. Investigations disclosed that dermatitis had developed among girls working on the lining, which was thought to be rayon. The number of cases of dermatitis reported was so great that both the women's suit manufacturer and the babies' coat manufacturer were compelled to recall all the suits and coats, remove the lining and replace it with other fabric. The trade journals and the manufacturers of the Fiberglass fabric were notified of this outbreak of dermatitis, and a warning was given against use of Fiberglass for clothing. Recently reports have been received of dermatitis occurring from glass fabric being used for binding seams in women's dresses.

Streptomycin for Treatment of Suppurative Otitis Media.—Holt and Snell used streptomycin in 20 cases of suppurative otitis media representing 26 ears infected with gram-negative organisms. Two Gm. of streptomycin was given daily for five days. The 2 Gm. of the drug was dissolved in 24 cc of sterile water and given in 2 cc. doses intramuscularly every two hours day and night. The ears were dried daily, and streptomycin drops were instilled into the external canals hourly throughout the waking hours. Complete drying of all discharge occurred in 50 per cent of the infected ears Improvement was noted in 31 per cent. Nineteen per cent showed no improvement. Tests for sensitivity to streptomycin revealed that the infecting organisms varied from 1 to 16 units per cubic centimeter. After treatment the organisms in the cases in which streptomycin failed to effect improvement proved to be resistant to .128 units per cubic centimeter. This suggests a rapid development of resistance to streptomycin.

Vitamin C in Gastric Resection for Peptic Ulcer.—The observations reported by de Jesus Zerbini were made on 2 vitamin C deficient patients with duodenal ulcer subjected to gastric resection. One with a total, though unsuspected, absence of ascorbic acid in white cells and plasma, without clinical manifestations and uncorrected by preoperative therapy, exhibited severe surgical shock during operation, which seemed to respond promptly to the intravenous injection of 2 Gm. of the vitamin. The other, with a known absence of ascorbic acid in plasma and white cells, completely corrected before operation, exhibited after operation a fall to zero in the plasma level, with no corresponding fall in the white cell level in spite of the daily injection of 200 mg. of the vitamin; on removal of stitches on the seventh postoperative day, the wound showed no evidence of healing. This suggests that a low or zero level of plasma ascorbic acid should not be looked on as harmless and that a sufficient amount should be given after operation in order to maintain a high plasma level.

Small Threaded Wires in Treatment of Fractures.—McCarroll discusses the use of small threaded wires in the treatment of fractures. The small size of the wire, the excellent fixation afforded by the threads and the minimum amount of trauma to bone and soft tissues render them superior to other forms of internal fixation in certain types of fractures. The method has been used for comminuted intertrochanteric fractures of the femur, for spinal or oblique fractures of the tibia and fibula and for fractures about the ankle joint. The small threaded wire can be used in fractures of the clavicle, in dislocation of the acromioclavicular joint, in fractures of the proximal end of the humerus, for fractures of the epicondyle of the humerus with displacement, in comminuted fractures of the lower end of the humerus with extreme displacement of the fragments, in fractures of the olecranon and in fractures and dislocations of the metacarpals.

Heparin and Dicumarol in Treatment of Deep Venous Thrombosis.—Holden presents a plan for the treatment of venous thrombosis embracing the physiologic principles underlying the use of and the indications for anticoagulant therapy, venous ligation and anesthesia of the paravertebral sympathetic system. Sixteen of 31 patients with venous thrombosis had pulmonary infarcts before the diagnosis of peripheral venous thrombosis was made. All 31 patients were treated primarily with subcutaneous administration of heparin and dicumarol. Five of the 31 patients had ligations of the superficial femoral vein, and 3 had paravertebral sympathetic blocks. All recovered.

Physiologic Responses in Trench Foot.—Burch and his co-workers aimed to find an objective test which would aid in determining whether or not patients who formerly had acute trench foot are still showing evidences of active disease. This study is based on the premises that trench foot is an inflammatory disease produced by exposure to cold and moisture and that tissue reaction and repair persist long after initial exposure. Temperature studies by means of skin thermocouples supplemented by evaluations of skin color and the rate of refilling of pressure emptied skin vessels were used to uncover local inflammation and the rate of circulation. The comparative rates of water loss from the skin of normal and trench foot subjects were also observed. There was practically no difference in sweating between normal and trench foot subjects. The initial temperature of the foot of the mild chronic trench foot subject was higher than that of the normal subject, and there was a direct correlation between the clinical severity of the disease and the height of this temperature. Trench foot subjects did not adapt to environmental cooling like the controls. This fact was demonstrated by studies conducted on the refilling time of pressure emptied skin vessels. An "activity index" based on the initial stabilization temperature, number of degrees temperature fall following fifteen minutes of occlusion and rise during hyperemia after release of the circulation can be devised to express the amount of inflammatory activity in a part injured by cold and moisture. Such an index might be further supported by data on the refilling time of pressure emptied skin vessels.

Elimination of Poliomyelitis Virus from Mouth or Nose.—Ward and Walters carried out tests on 19 patients in the early stages of poliomyelitis. Virus was demonstrated in material expelled from the mouth or nose of 2 of the 19 patients. This was achieved by having patients blow and spit into cloth masks from which virus was extracted. Virus was also detected in nasal swabs of the first patient and pharyngeal swabs of the second patient shown to have eliminated virus from the mouth or nose. In 5 additional patients virus was isolated only from swabs of the pharynx. This is believed to be the first demonstration of virus elimination from mouth or nose under circumstances which come fairly close to being natural.

Pneumoperitoneum with Diaphragmatic Paralysis in Treatment of Pulmonary Tuberculosis. D. J. Gilmore.—p. 153.

Physiologic and Antibiotic Therapy in Pulmonary Emphysema.—Of 86 courses of treatment administered by Barach and Garthwaite in 51 cases of pulmonary emphysema, clinical improvement attributable chiefly to penicillin, administered as an aerosol in most cases and with systemic administration in resistant cases, was definite in 20, moderate in 19 and slight in 25; in 22 no improvement took place. The results of physiologically directed therapy, a combination of periodic administration of aminophylline and epinephrine, bed rest, administration of meperidine hydrochloride (demerol), manual compression of the upper abdomen underneath the ribs during the latter part of expiration and inhalation of 70 to 100 per cent oxygen for twenty to thirty minutes two or four times daily, in the same group were definite improvement in 9, moderate in 36, slight in 23 and none in 18. Of a total of 86 courses, 66 patients manifested moderate or pronounced improvement. In analyzing the role played by each therapeutic factor, 31 of the 66 improved cases appeared to be more influenced by physiologic therapy and 27 by penicillin treatment, with an equal effectiveness in 8 cases. In some of the cases in this series previous exposure to physiologic therapy had resulted in a baseline of improvement which gave the appearance of less striking effect from this type of therapy than might have been anticipated in cases in which the procedures used in bronchial relaxation and inhalational therapy had not been employed. The study of the sputum culture before and after treatment revealed the characteristic disappearance of gram positive organisms in the majority of cases with replacement by gram negative bacteria.

Treatment of Thoracic Empyema.—Tonolla and Brantigan employed sodium tetradecyl sulfate 1: 500 in azochloramid 1: 3,300 in the treatment of 7 patients subjected to aspiration of the pleural cavity with instillation of this chemotherapeutic agent. The effect of this substance is to lower surface tension, thereby allowing better penetration of the antiseptic agent, and to facilitate the removal of the exudate. The solution tends to prevent reformation of intrapleural fluid while sterilizing the area. These patients recovered and remained well. If the infection is not eliminated in three to six days, as it happened in the seventh case, either closed or open thoracotomy should be resorted to. Twenty-eight patients were treated with closed drainage and 20 patients with open thoracotomy. In none has there been a chronic empyema.

Treatment of Sensitive Hay Fever Patients.—Lazarowitz thinks that the disadvantages of treating hay fever patients with injections are due in many instances to the too rapid absorption of the antigen, especially in those most sensitive. Many attempts have been made to slow the absorption of pollen extracts by the addition of various substances known to cause delay. The principle of chilling is presented as a new approach to solve the problem of slow absorption of allergenic extracts. A small ice bag supported by a bandage was applied to the midouter part of the arm for fifteen minutes prior to and for fifteen minutes subsequent to the subcutaneous injection of ragweed extract to retard the circulation in and around the site of the injection. Thirty hay fever patients were treated with dosages exceeding three to four times the routine dosage of ragweed extract due to the retardation of absorption following the vasoconstriction of chilling. The chilling procedure is time saving, since it diminishes the number of visits by 40 per cent. Constitutional reactions occurred seldom, and no delayed reaction was observed. The treatment gave effective relief of symptoms of hay fever in all treated patients. Chilling renders the injections painless.

Penicillin in Intractable Asthma.—Miller reports observations on 26 adults and 3 children to whom penicillin was administered at three hour intervals in doses of 12,500 or 25,000 units. The average total dose was 1,000,000 Oxford units. Eleven of the 29 patients showed an excellent response while receiving penicillin; they became symptom free or so nearly so that they required no symptomatic therapy. Eleven showed improvement but continued to require occasional, although less frequent, symptomatic treatment. Seven showed no change whatever either during the hospital course or thereafter. Penicillin cannot be considered a panacea for intrinsic asthma. It should be regarded as a treatment of infectious processes and as such seems to be effective in selected cases of bacterial asthma.

Steroid Hormones in Osteoporosis.—Reifenstein and Albright studied the effect of certain steroid hormones, notably estrogens, androgens and progesterone, in 11 cases of osteoporosis: 5 cases of the postmenopausal type, 1 case of the senile type, 2 cases of the type seen following orthopedic operations (atrophy of disuse) and 3 cases of the Cushing's syndrome type. Estradiol benzoate and diethylstilbestrol decreased the calcium and phosphorus excretions in the four types of osteoporosis studied. Testosterone propionate and methyl testosterone decreased the calcium and phosphorus excretions in the postmenopausal, senile and Cushing's syndrome osteoporosis. Progesterone in the dosages of 10, 25 and 100 mg. daily had no effect whether given alone or in combination with an estrogen. The effect on the calcium metabolism of estrogen and androgen in combination was greater than that of either alone in the postmenopausal and senile groups. In Cushing's syndrome estrogen probably does have a beneficial effect on the calcium balance, previous statements to the contrary from this clinic notwithstanding. Testosterone compounds have a much more striking effect in this condition, as opposed to other types of osteoporosis.

Pamaquine Naphthoate as Prophylactic for Malarial Infections.—"Pamaquine" is the term the United States Pharmacopeia applies to plasmoquine, 6-methoxy-8-(1-methyl-4-diethylamino) butyl-aminoquinoline. Feldman and his associates administered pamaquine naphthoate to 36 patients with dementia paralytica as a prophylactic against mosquito induced infections with Plasmodium vivax and Plasmodium falciparum. Daily doses of either 160 or 180 mg. administered the day before, the day of and for five or six days after the day of inoculation with P. vivax have prevented or postponed the primary attack for months. In the case of P. falciparum postinoculation treatment could be shortened to three days with similar results, except that delayed primary attacks were not observed. Two instances of acute hemolytic anemia were encountered among 11 Negro patients. One of these was reexposed to the drug and promptly had another hemolytic episode. Methemoglobinemia was regularly encountered in all subjects. Elevations of the serum bilirubin and moderate hematocrit decreases were commonly noted among those receiving the higher, more prolonged courses, regardless of race. Pamaquine naphthoate is rapidly absorbed and excreted.

Duodenal Ulcer Following Exposure to Carbon Tetrachloride.—In the 2 cases of carbon tetrachloride poisoning reported by Smith, duodenal ulcer followed exposure to toxic concentrations of this solvent. In neither case had there been any previous history of digestive disturbance. While it is recognized that silent cases of ulcer do occur, the development in both these instances of ulcer symptoms following promptly on severe exposure is believed strongly suggestive of a causal relationship. A review of case histories of carbon tetrachloride poisoning suggests that the development of peptic ulcer, even though infrequently reported, may not be an uncommon complication.

Loose versus Close Fitting Clothing for Work in "Tropical Heat."—Yaglou and Rao carried out tests which demonstrate that in tropical heat, when solar radiation is not a factor, *any clothing is a hindrance to loss of body heat.* If clothing must be worn it should be loose fitting and of light weight; it should expose as much skin area as possible and *should be designed for maximum ventilation. Clothing designed* for skin ventilation by "bellows action" is more efficient for evaporative cooling during work in tropical heat than is a close *fitting absorbent garment.*

Poison Oak Dermatitis.—Templeton and his co-workers studied the effect of severe poison oak dermatitis on the temperatures and blood counts of 106 patients. Of 79 patients who could give an exact date of exposure the first lesions were noted within twenty-four hours by 54 patients. In 60 of the patients the dermatitis required three to five days from onset to reach its greatest intensity. Little systemic reaction takes place in severe poison oak dermatitis. About four fifths of the patients reacted with slight fever. About half had a mild leukocytosis and about half had a moderate *eosinophilia.* The urines of all patients were normal.

Effect of Prolonged Ingestion of Thiourea on Mammary Tumors in Mice.—Virgin strain C3H mice aged 11 months without palpable spontaneous mammary tumors were divided by Morris and his associates into two groups. One group was placed on a stock diet of natural foodstuffs to which was added thiourea. The animals ingested thiourea until mammary tumors developed, or from a minimum of two to a maximum of sixty-three weeks. The control group was maintained on the stock diet throughout. The incidence of spontaneous mammary tumors was essentially the same in the two groups. The appearance of the tumors was delayed in the thiourea treated group. The average time till tumors appeared was 16.2 weeks in the treated group and 8.7 in the control, a statistically significant difference.

Surgical Treatment of Angina Pectoris.—Lindgren and Olivecrona state that in 7 patients whom they treated by section of the five superior dorsal roots the results were not gratifying. Most patients had moderate relief from pain, but none were completely or permanently free from discomfort. In some patients attacks of angina pectoris returned; 1 patient had a constant feeling of oppression in the chest and another developed anesthesia dolorosa. Resection of the stellate ganglion according to Leriche was employed in 2 patients, in whom moderate improvement was obtained. Of a series of 250 patients with cardiac pain, 71 patients were selected for resection of the stellate and the four upper thoracic ganglions. Operative indication was severe angina pectoris resistant to medical treatment. Two cases of cardiovascular syphilis were included. Three patients died during the operation, 2 of them probably from myocardial infarction and 1 from valvular pneumothorax. In 8 other patients myocardial infarction occurred within one month after the operation. In 3 of them the infarct was fatal. The most common complication was painful neuritis, usually of short duration. Transient phrenic nerve paralysis was observed. The "migration of pain" phenomenon was observed. In 1 case in which the anginal pain had migrated to the jaws, bilateral tractotomy gave an excellent result. The results of the extensive cervicothoracic ganglionectomy were gratifying. The operation gave complete or nearly complete relief from pain in 44 per cent, and in 41 per cent it converted severe forms of angina pectoris into milder types. The sensation of fear connected with the pain disappeared in many patients. On emotion or exercise all patients postoperatively experienced a choking sensation or slight pain, which served them as a "warning signal."

Work After Carbohydrate Meals.—Haldi and Wynn describe studies which revealed that work output, muscular efficiency and percentage recovery (measured by a comparison of the work performance in the first and second exercise periods) were not diminished by a high carbohydrate intake two to three hours before exercise. After a meal rich in carbohydrate the blood sugar level immediately before exercise was higher than at the corresponding time after the low carbohydrate meal. The data of these experiments are offered as confirmatory evidence for the conclusion drawn from other observations that a hypoglycemic reaction is not the usual physiologic response to a high carbohydrate meal.

Improving Nutritive Value of Flour.—Westerman and Hall describe experiments carried out to determine the effect of supplementing enriched flour with other B complex vitamins. Evidence is presented to show that the addition of riboflavin, thiamine, calcium pantothenate and pyridoxine to enriched flour improves the nutritive value.

Obstructive Laryngitis Caused by Hemophilus Influenzae Bacillus Type B.—Davis thinks that the importance of laryngeal infections caused by Hemophilus influenzae bacillus type B in children is not generally recognized. Unless the clinical features of this rapidly developing infection are recognized, in many instances proper treatment will not be instituted in sufficient time to prevent death. The onset is abrupt. The child becomes fretful and complains of a sore throat accompanied with difficulty in swallowing. There develops in extremely rapid progression respiratory distress with inspiratory retraction of the sternum and soft tissues, cyanosis, hoarseness and a croupy cough. Prostration is out of proportion to the short duration of the illness. The children are frequently limp, in shock and moribund within eight to twelve hours after the onset of symptoms. The temperature ranges from 100 to 104 F. Examination of the oropharynx usually shows that it is intensely red and edematous. The epiglottis and glottis are swollen and fiery red. Membranes are notable by their absence. The principal laboratory findings are leukocytosis of 15,000 cells or more and a polymorphonuclear leukocytic count of 80 or 90 per cent. The diagnosis can be confirmed by recovering H. influenzae type B in cultures taken from the nasopharynx, the oropharynx, the larynx or the blood. The three cardinal therapeutic measures to be executed should include the performance of a tracheotomy for relief of respiratory obstruction, the administration of sulfadiazine and type B H. influenzae rabbit antiserum, and the administration of parenteral fluids to combat or prevent shock. Davis presents 3 illustrative cases.

*Environment and Fatal Heat Stroke: Analysis of 157 Cases Occurring in the Army in U. S. During World War II. Elizabeth Schickele. —p. 235.

Environment and Fatal Heat Stroke.—Schickele analyzes 198 cases of heat fatalities suffered by soldiers in training in the United States from 1942 to 1944 and made available by the Army Institute of Pathology. From these, 157 were selected in which no cardiac or other disease or other effect which would predispose to increase in body temperature could be found, and in which therefore death might be presumed to have been due only to the effects of exposure to heat. Heat deaths are found to be caused by the heat load, as determined by climate, activity and body build. These factors cannot be considered separately but must be treated as components of the total heat stress. A considerable amount of the variation of the weather conditions under which individuals became ill may be attributed to the interaction of all factors influencing heat stress. "Rapid acclimatization" of one week or ten days cannot be expected to confer complete immunity to heat injury for men who are working in the sun during the heat of the day, when weather conditions exceed those of the "heat death line." One third of the patients who died had spent a month or less in the heat before death occurred, with as many deaths after four weeks' exposure as after one week's exposure. Incidence fell off rapidly for longer acclimatization periods. Susceptibility to heat stroke appears to be particularly high among persons acclimated to an atmospheric cooling power above a certain level (about 600 calories hourly per square meter of body surface) when they are exposed to an atmospheric cooling power reduced below this level. A map is drawn showing three cooling power zones in the United States. In the most northerly, the heat stress on the average is apparently not sufficiently high to confer acclimatization for work in the sun when conditions are more severe than those of the "heat death line." Persons living in this zone will therefore be particularly susceptible to heat injury during unusual heat waves or excursions to hotter climates. Most fatalities associated with heavy exercise occur at relatively low temperatures, when the total heat stress is commonly underestimated.

Fractures Following Electroshock Therapy.—Lingley and Robbins report the results of a study on 230 patients who had received electroshock therapy varying from a single treatment to several series of treatments. The convulsions lasted about forty-five seconds, during which the patient was held by five attendants. The attendants were experienced and realized the importance of not holding the subject too rigidly. Fifty-three, or 23 per cent, sustained fracture, predominantly of the vertebrae. The incidence of fracture was greater in males than in females, and in the younger and older rather than in the middle age groups. It seems that whether the convulsion is due to tetanus, epilepsy, therapeutic metrazol and allied drugs or to electroshock the number of bones fractured and the areas involved are probably dependent to a great extent on the severity of the convulsion. Bone conditions that appear to contraindicate shock therapy include osteoporosis, malignant lesions, Otto's pelvis, possibly Paget's disease, and syphilitic lesions.

Control of Streptomycin Therapy.—Aikawa and his associates point out that streptomycin is the most useful drug available at present for the treatment of tularemia, influenzal meningitis and urinary or blood stream infections due to gram-negative bacilli. In vitro testing for susceptibility is useful before therapy is begun and in cases in which cultures remain positive. Infections should be treated vigorously from the start, and therapy should be controlled by laboratory methods. The dose and mode of administration must be individualized for systemic infections. For urinary tract infections doses of 1 to 2 Gm. daily are usually effective. The drug should be continued at least three days; if the patient has not improved after five days, the organism has probably acquired resistance and further therapy may be ineffective. Streptomycin is more effective in an alkaline medium; therefore, in urinary tract infections, the p_H of the urine should be increased to 8, if possible. Resistance to the drug develops rapidly and, once developed, it is permanent. Because resistance develops frequently in urinary tract infections complicated by obstruction to urine flow or the presence of a foreign body, it may be advisable to use other chemotherapeutic agents first and to reserve streptomycin for postoperative use.

Effect of Infusion Fluids and Diuretics on Anuria Resulting from Burns.—Olson and Necheles produced acute anuria in dogs. Plasma and saline solution were the least effective infusion fluids for combating the anuria. In increasing order of effectiveness were sodium lactate, 5 per cent dextrose in isotonic solution of three chlorides, 2 per cent urea in saline solution and 0.9 per cent saline solution with 0.87 per cent sodium bicarbonate. They were effective in instances in which kidney damage was not great. Isotonic solution of sodium sulfate was the most effective agent in combating burn anuria. The use of isotonic solution of sodium sulfate is recommended in the treatment of the anuria of burns and of related anurias.

Unilateral Exophthalmos in Thyrotoxicosis.—Kisner and Mahorner report 5 cases of unilateral exophthalmos due to toxic diffuse goiter. In all of these cases the unilateral exophthalmos was a prominent sign and in some it was the only one noticed by the patient. The cause of exophthalmos is not established, but from experimental studies it would appear that a factor in the anterior pituitary secretion has the property of producing exophthalmos, and the same or a different factor has the property of inducing hyperplasia of the thyroid gland. The erroneous impression exists that the exophthalmos immediately subsides following thyroidectomy, but even in cases with high basal metabolic rates the exophthalmos is frequently a little worse in the weeks immediately after the operation. Only after many weeks and months does the exophthalmos gradually subside. Because of the long time over which improvement in exophthalmos after thyroidectomy may occur, radical procedures such as the Naffziger operation should be deferred unless extreme proptosis greatly jeopardizes the sight of the eye.

The Advantages and Limitations of Thiouracil in Thyrotoxicosis.—According to Fowler and Cole, thiouracil reduces the basal metabolic rate to normal in at least 95 per cent of patients with hyperthyroidism. In a study of 1,543 cases collected from the literature, reactions were noted in 13.8 per cent of patients treated. The most serious reaction was agranulocytosis, which was encountered in 0.78 per cent of patients. Although much less serious, leukopenia was more common. Vomiting, dermatitis and pruritus also were encountered. Other reactions included purpura, localized edema, arthralgia and swelling of the salivary glands. The mortality rate of 0.45 per cent seems a serious disadvantage. In the 79 patients treated by the authors, reactions were slightly greater in number but less in severity than has been reported in the literature. The greatest advantage of thiouracil over iodine is in patients who are so toxic that bilateral thyroidectomy is unsafe under iodine therapy. The drug is particularly useful in patients with cardiac decompensation secondary to hyperthyroidism. Patients with mild toxicity and small glands are more apt to have permanent remissions than do other types. Patients with toxic diffuse goiter respond slightly better than do those with toxic nodular goiter. The most serious disadvantage is the toxicity and particularly the mortality rate.

Thyroid Tumors in Rats Treated with Thiourea.—*Purves and Griesbach found that prolonged administration of* thiourea to rats caused formation of thyroid adenomas After months of treatment 7 out of 13 of these tumors showed the histologic appearance of adenocarcinomas Invasion of the blood vessel walls was visible in all 7 cases. In 2 of these cases lung metastases of thyroid tissue were found In 3 thyroid tumors, 2 of which were malignant, solid masses of cells were found which resembled human "fetal adenoma" It is considered that these growths were derived from the cancerous tissue The thyroid adenomas observed in these experiments retained in full their ability to respond to fluctuations in thyrotropic stimulation.

*Atelectasis After Partial Gastrectomy. P. Stringer.—p 289.
*Pain and Healing of Peptic Ulcers A. M. Gill.—p 291.

Compression of Median Nerves in Carpal Tunnel.—Brain and his associates describe 6 patients, all middle aged or elderly women, who had bilateral median neuritis due to compression of the nerves under the transverse carpal ligament at the wrist The symptoms were pain, paresthesia and cutaneous sensory loss within the distribution of the digital branches of *the median nerves, and partial thenar atrophy limited* to the abductor brevis and opponens pollicis muscles or even the abductor brevis alone. All were treated by surgical division of the transverse carpal ligament with immediate relief of pain and tingling and gradual improvement in power and diminution in sensory loss. The lesion found at operation was compression of the nerves in the carpal tunnel and edema for about 1 inch proximally. Extension of the wrist raises the pressure in the carpal tunnel Occupations involving this movement may in time lead to compression of the median nerves. In housework, particularly in scrubbing and polishing, the hand holding the brush or the cloth is usually extended at the wrist and the other hand often rests with the palm on the flat surface and the wrist also extended The authors stress the need of differentiating this syndrome of compression of the median nerve in the carpal tunnel from costoclavicular syndromes.

Atelectasis After Partial Gastrectomy.—Stringer investigated the incidence of atelectasis after partial gastrectomy by radiography of the chest immediately after, four hours after and twenty-four hours after operation in 55 cases Twenty-six showed abnormal postoperative radiologic signs, and 13 showed signs of lobular, partial or total atelectasis. Signs first appeared radiologically at four hours in 5 cases and at twenty-four hours in a further 6 cases. The other 2 cases of atelectasis did not develop until later. Besides signs of atelectasis there were increased vascular markings in some cases, and 3 other cases showed bronchopneumonia, bronchitis and collapse with effusion The film taken twenty-four hours after operation is the most valuable in determining whether or not atelectasis has occurred If the cause of atelectasis is bronchial occlusion by a mucous plug, bronchoscopy should be considered.

Pain and Healing of Peptic Ulcer.—Gill cites examples of the erratic nature of the pain in patients with peptic ulcer. Severe hemorrhage and the presence of a comparatively large crater may at times be unaccompanied with pain, whereas in other cases the ulcer may heal and the pain continue as it does in phantom limb The factors that cause an ulcer to heal are not easier to understand Ulcers are not healed by diet alone, by injections or by medicines but because the man with the ulcer comes under the care of a physician who is able to transmit some of his own confidence to his patient

Tuberculin Surveys and the Tuberculin Test. B. Couts —p. 42.
*Treatment of Minimal Tuberculous Chest Lesions. Comparative Study. R Heller.—p 49.

Minimal Tuberculous Chest Lesions.—Heller thinks that, *owing to the detection of an increasing number of minimal chest* lesions by *mass x-ray surveys*, their treatment assumes great importance Patients were selected whose tuberculosis had been regarded as quiescent after having received institutional treat*ment for small,* active unilateral lesions. There were 55 such patients who had been under observation for over one year to eight years. Thirty-four patients had received only bed rest and routine sanatorium treatment. Of this group 17 patients relapsed, 2 of them twice. Twenty-nine patients received collapse treatment, 8 of these after having relapsed after a period of routine sanatorium treatment. None of the 29 patients in this group relapsed; all of them were well and working, and there were no complications. The policy of withholding collapse treatment in active minimal lesions because of a negative sputum and absence of cavitation appears unjustifiable. The duration of institutional treatment was longest for the collapse therapy group. The average time off work for the successfully treated patients was nearly twelve months. The patients who relapsed had only an average of eight months off work. The author believes that many relapses could have been avoided by earlier institution of collapse treatment.

Syndrome of Anterior Spinal Artery. D. Louis-Bar.—p. 40.
Genetic Causes of Schizophrenic Symptoms. E. Slater.—p. 50.

Rheumatic Facial Paralysis?—Winternitz analyzed histories of patients admitted to the clinic in Leiden between 1934 and 1945. Among 233 patients with peripheral nontraumatic facial paralysis 24 had a history suggesting that rheumatism possibly had occurred beforehand, while among 136 parallel patients without peripheral facial paralysis 41 had rheumatism. Conversely, among 200 patients with rheumatism chosen at random, not 1 was found with a history of peripheral facial paralysis. The author concludes that most attacks of nontraumatic facial paralysis arise from unknown causes and that the rheumatic nature of the condition has not been demonstrated.

Follicular Keratosis and Vitamin Deficiency. E. Pulay.—p. 239.

Radioactive Isotopes for Localized Radium Therapy.—Muller says that radioactivity diffused through the entire organism can be obtained by administering radio sodium (N^{24}) or radio phosphorus (P^{32}) by ingestion or by intravenous injection. He demonstrates a method permitting the application of the radioactive isotope radio zinc (Zn^{63}) in order to achieve a localized radiotherapeutic action. In order to avoid diffusion of the isotope outside the region of application, the radio zinc is suspended in a macrocellular medium with a pectin base. Interesting palliative results have been obtained with this method in a small number of cases with extensive peritoneal carcinosis. It is possible with this method to make intratumoral and peritumoral radioactive infiltrations without diffusion of the radioactivity outside the site of application. The method is still in the initial stage. Its employment on a larger scale depends on being able to obtain radioactive isotopes in sufficient quantities. It is also desirable to obtain isotopes with a more prolonged action than radio zinc.

*Intoxication by Hydrocarbons: Cases. A. Crisci, A. Rodriguez and J. J. Scandroglio.—p. 1.

Intoxication with Hydrocarbons.—Two adult patients with pulmonary tuberculosis and bilateral pneumothorax were given intravenous injections of 4.5 and 10 cc. respectively of kerosene from a flask labeled calcium chloride. The immediate symptoms were those of violent cough, suffocation and cyanosis followed by blackish expectoration, fever and mental confusion. The predominant symptoms were those of toxic pulmonary alveolitis. Roentgenograms of the chest showed fat miliary nodules in both lungs, especially in the normal lung. Decompression of pneumothorax was carried out in 1 patient and 120 cc. of serohemorrhagic pleural liquid was removed from the other. The toxic symptoms subsided in two weeks. Roentgenograms of the chest six and fifteen months later showed that the intoxication had neither a harmful nor a beneficial effect on the course of tuberculosis.

Blood Transfusion and Coagulation Time. A. S. Benchimol.—p. 154.

Solubility of Curare Preparations When Added to Sodium Pentothal.—Formation of a white precipitate when curare and pentothal come in contact is the chief obstacle to their simultaneous administration. Collados Storni believes that the formation of the precipitate depends on the concentration and purity of the curare solution. He found that the following four solutions of curare can be added to 10 cc. of a 2.5 per cent solution of sodium pentothal without producing a precipitate: 0.8 cc. of intocostrin, 0.6 cc. of curare extract (Lilly), 2.4 cc. of fraction 21 A of curare extract (Abbott) or 3 cc. of solution of d-tubo curarine. The d-tubo curarine equivalents of the curare content per cubic centimeter in these pentothal-curare mixtures are respectively 0.22, 0.17, 0.580 and 0.69 mg. When protected from air and kept at a temperature of 4 C. the compatible mixtures of these solutions of pentothal and curare remain liquid and retain their pharmacologic properties for longer than a week.

Cerebral Atrophy. H. L. Plaza.—p. 816.

Subcutaneous Implantation of Testosterone.—Vargas and Lucchini review 78 cases in which 125 implantations of testosterone tablets were performed. In women with carcinoma of the breast, pains in the bones disappeared, there was an improvement in the general condition and the period of survival was lengthened. In patients with uterine fibromyoma there were suppression of metrorrhagia, reduction in the size of the tumor and temporary amenorrhea. The tablets effected considerable improvement in the general condition in the male climacteric. In patients with prostatic adenoma, dysuria and the size of the tumor decreased. Growth of the genitalia was observed in 1 patient with male hypogonadism, but of 6 patients with impotence only 1 noted improvement. In 2 patients with adrenal insufficiency weight and blood pressure improved and tachycardia and weakness decreased. Favorable results were obtained in functional menorrhagia in that either the menstrual cycle became regularized or transitory amenorrhea resulted. In patients with fibrocystic mastitis pain and the tumor disappeared and recurrences were prevented.

Neostigmine in Paralysis Following Cerebral Trauma.—Grashchenkov injected neostigmine one or more times in nearly 300 cases of cerebral trauma with paralysis. In most cases there was immediate and lasting motor and sensory improvement; in some this was striking, and in only 6 per cent was no improvement observed. The author concludes that neostigmine corrects functional asynapsis—the functional elimination of structural intact nervous elements exposed to the toxic autolytic products of adjacent destroyed tissue. It is presumed that neostigmine exerts a direct beneficial effect on the altered enzymatic processes in these poisoned tissues as well as an indirect effect via the vegetative nervous system.

Lymphatic System in Antivirus Immunity.—Comparative studies were made by Gaidamovich and Soloviev between the anti-influenzal titer in the lymph, lymphocytes and lymph nodes and the amount of antibody circulating in the blood. The studies which were made on rabbits revealed that the amount of anti-influenza antibody in the lymph of rabbits immunized with influenza virus is proportional to that in blood. The antibody titer in lymph is some 60 per cent of that in the blood. No antibody has been found in the cellular elements of lymph. When antigen is introduced into rabbits, the regional lymph nodes contain the corresponding (anti-influenza) antibody regularly, although in small quantities. In view of the fact that antibody is linked with the globulin fraction of protein, it is to be expected that the amount of antibody in the lymph is proportional to its content of globulin. This has been confirmed in experiments with bacterial agglutinins, hemolysins and antitoxins and by the described experiments on anti-influenza antibody. Similar results were obtained in preliminary investigations on the lymph antibody level in animals immunized with other viruses, such as virus of equine encephalomyelitis and of silver fox encephalitis. The negative results regarding the content of anti-influenza antibody in the cellular elements of lymph are at variance with the theory of antibody formation in lymphocytes.

New Type of Vaccine from Typhus Lice.—Pshenichnov and Raikher succeeded in developing a simple method of infecting lice with typhus by artificial feeding of the bloodsucking insects on epidermal membranes obtained from cadavers. The membrane is stretched over a feeding camera. Under the stretched membrane defibrinated blood is introduced, to which are added crushed lice containing the typhus virus. The larvae spread on the surface of the membrane speedily attach themselves and begin to feed. In the apparatus constructed by the authors, which contains twelve feeding cameras, 60,000 to 200,000 larvae can be fed simultaneously. The development of the virus and the appearance of enormous quantities of rickettsias both within and outside of the cells takes place on the eighth or ninth day. From the moment of infection to the moment of development of virus the larvae are fed twice daily on donor convalescents for twenty minutes at a time. After the fifth day of infection smears are prepared daily from each batch of larvae. The development of virus can be gaged by the staining of the rickettsias. The authors describe the preparation of the vaccine and discuss its antigenic properties. They stress that this new method of preparing typhus vaccine from lice is cheaper and simpler than the Weigl method and can be applied on a large scale. The vaccine when tested on human beings caused little reaction. It protected persons exposed to small doses of virus but not to massive doses. Typhus is mild in the vaccinated.

New Blood Albumin Substitute.—A protein substitute for blood was worked out by Fedorov with the introduction of nonanaphylactogenic foreign protein which was obtained from milk casein. This protein can be used for intravenous injections and for repeated introduction in large doses without harmful effects. The solution can be used for substitution or stimulation therapy.

Congenital Defects of Forearm: Bilateral Radioulnar Synostosis. A. Van Der Sar.—p. 313.
*Special Form of Hyperchromic Macrocellular Anemia. G. M. H. Veeneklaas.—p. 316.

Prevesical Prostatectomy According to Millin.—Bakker and van Gulik employed Millin's retropubic method in 32 cases with 1 fatality. The method is technically easier than the one of Young and McCarthy, its mortality rate is low, convalescence is less trying for the patient as well as for the nursing personnel and the time in which postoperative care is necessary is shorter. Millin's retropubic, prevesical method of prostatectomy is a valuable addition to the surgical methods for hypertrophy of the prostate.

Special Form of Hyperchromic Macrocytic Anemia in Nurslings.—Veeneklaas observed a hyperchromic macrocytic anemia in 2 children who were about 1 year old. The diet of both these children had contained neither greens nor fruit. There was also dystrophy, enlargement of liver and spleen, urobilinuria and an increased indirect Hijmans van den Bergh test. The addition of fresh vegetables and fruit to the diet of 1 patient was followed by a rise in reticulocytes in ten to fourteen days; in the second patient the addition of fresh endive had the same effect. Complete recovery resulted in six to eight weeks.

Centenary of Ether Anesthesia. G. Lijestrand.—p. 2951.
High Stomach Resection in Ulcer and in Gastritis. H. Wahren.—p. 2958.

Functional Changes in Electrocardiogram in Neurocirculatory Asthenia.—Burstein studied the electrocardiograms of 136 patients with neurocirculatory asthenia. Psychic strain is an important immediate cause; exhaustion and other factors, especially acute infections, are also significant. In some cases defective coronary circulation may play a part. There is practically always a sympathicotonic influence affecting the whole heart; the heart rate is considered an indicator of its tone. On increasing heart rate the PQ interval shows a reduction in lead 1 and remains constant in leads 2 and 3. P_1 is not notably affected by the heart rate, but P_2 and P_3 rise continuously on increasing heart rate. The fairly common occurrence of P pulmonale is the electrocardiographic expression of increased influence of the sympathetic on the whole heart. The T waves become lower on the average as the rate increases, reduction of T_3 occurring only with the highest rate. Axis deviation, bodily structure, emphysematous changes and cor parvum have but little effect on the height of the P and T waves.

Book Notices

Heparin in the Treatment of Thrombosis: An Account of Its Chemistry, Physiology and Application in Medicine. By J. Erik Jorpes, M.D., Reader in Biochemistry, The Caroline Institute, Stockholm. With a foreword by J. R. Learmonth, C.B.E., Ch.M., F.R.C.S.E., Professor of Surgery, University of Edinburgh, Edinburgh. Oxford Medical Publications. Second edition. Cloth. Price, $6.50. Pp. 260, with 22 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4., 1946.

More than seven years have elapsed since the publication of the first edition. Seven years ago the author wrote sixteen pages on the clinical application of heparin, the rest of his treatise being devoted to the discovery and chemistry of heparin, to which he had made such notable contributions. This edition not only enlarges on the theoretical considerations but is a detailed statistical record of the clinical applications of heparin and its rival anticoagulant dicumarol. It appears from the figures of Swedish clinicians that not only has the mortality of thromboembolism been cut to a minimum by the use of heparin, not only has the prophylactic use of the anticoagulant prevented thrombosis to a very appreciable degree, but the proper and early use of heparin has throttled the appearance of the late sequelae of thrombosis, the indurations, ulcerations and disabilities, which are a serious economic drain on the patient and the community.

Perhaps the most striking virtue of the treatise is the way it fills the gap between the facts of pure chemical research and its clinical application. Because of the work of the Swedish group headed by Jorpes and Craafoord and the Toronto group of Best and Murray, the physician of today has been presented in heparin with a drug as specific for thrombosis as insulin is for diabetes. There is no field in medicine in which heparin and also dicumarol could not be used in saving lives, decreasing morbidity and eliminating long-lasting disabilities due to thromboembolism.

There is a great lesson to be learned from this book, which incidentally is beautifully printed and illustrated: the value of cooperative research of the Swedish institutions, which, in spite of a population of little over six million inhabitants, has furnished such a mass of statistics.

Jorpes finishes his book with an interesting comparison. Between 5,000 and 6,000 persons are injured every year by automobiles in Sweden. The same number of thromboses occur annually in that country, and one has every reason to believe that the sequelae in the thrombotic group were more severe. As a prophylactic and early therapeutic measure, heparin assumes increasing social and economic significance.

Der Rhesusfaktor: Seine theoretische und praktische Bedeutung. Von Prof. Dr. G. Fanconi, Direktor der Universitäts-Kinderklinik, Zürich, et al. Paper. Price, 10 Swiss francs. Pp. 160, with 23 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel, 1946.

The Rh factor was discovered in this country by Landsteiner and Wiener in 1940. Soon afterward Wiener described its relation to blood transfusion reactions and Levine to fetal erythroblastosis. Only after the war have articles on this subject begun to appear in European continental literature. The monograph is made up of seven papers read at a meeting of the Zurich Pediatric Society on Nov. 30, 1945. The first chapter, by Fanconi, is a brief eight page review of the clinical significance of the Rh factor. The antigenic blood group structure of the human red cell is reviewed by Grumbach in the second chapter. The next chapter, by Zwingli, on experiences with the Rh factor in the Zurich Children's Hospital, deals mainly with the relation of icterus gravis to residual disturbances of the central nervous system (so-called kernicterus). E. Ziegler's 50 page chapter is a keen analysis of the pathogenesis of fetal erythroblastosis (the term "hemolytic disease of the newborn" is used in the monograph). The role of hemolized blood, of hepatic and capillary damage and of allergy is discussed in great detail. Liver therapy beginning early in pregnancy (second or third month) is recommended as a means of preventing the disease in the fetus. Specifically devoted to therapy of fetal erythroblastosis is Willi's contribution. He recommends continuous drip infusion of a fluid regrettably called by its trade name Tutofusin (possibly similar to isotonic solution of three chlorides). From 200 to 250 cc. is given daily for not more than three days. In connection with recent recommendations of replacement transfusions, reference to its use by de Lange in 1934 is worth noting. The final two chapters, by Zollinger, are no doubt the most important of the book. His well illustrated discussion of the gross and microscopic changes in fetal erythroblastosis is thorough, complete and lucid. Well presented is the correlation of biliary cirrhosis in the infant and child with hepatic damage in erythroblastosis based on a study of 30 cases. The Swiss writers are on the whole familiar with American and British publications, but some glaring errors have crept in: the discovery of the relation of the Rh factor to erythroblastosis is credited by Zollinger to Broman, who reviewed the subject in 1944, four years after Levine's publication. Similarly Foord and Fiske's observation that animal anti-Rh serums fail to distinguish between Rh-positive and Rh-negative erythrocytes of the newborn is also erroneously attributed to Broman by Ziegler.

The Theory of Human Culture. By James Feibleman. Cloth. Price, $5. Pp. 361. Duell, Sloan and Pearce, 270 Madison Ave., New York 16, 1946.

The science of medicine has become more and more related of late years to the social sciences. The concept of psychosomatic medicine demands of the physician a thorough knowledge of philosophy and psychology as well as sociology. This volume presents cultures of primitive peoples with a view to determining the evolution of present civilized customs and mores. Attention is given to the Maya and Pueblo Indian cultures and to a group known as the Baiga. Baiga culture emphasizes the essential freedom of the individual.

An interesting chapter deals with the mythology of modern science. The work concludes with an analysis of an advanced culture, that of England, and with a chapter devoted to preventive psychiatry. The author feels that the practical merit of the psychoanalytic procedure is undeniable even though the metaphysical claims that have been advanced for it by its founder and his loyal followers cannot be admitted. He concludes:

"Psychoanalysis through interview, free association, and the analysis of dreams analyzes those psyches in which falsity exceeds truth in action, where the criterion is social agreement. Common sense by comparison analyzes those psyches in which truth exceeds falsity in action, by the same criterion. Psychoanalysis is a method for treating the mentally sick. Common sense analysis is a method for improving the knowledge of those who are averagely well. The task of common sense analysis is numerically by far the greater. Since every one has an unacknowledged philosophy, it is always possible for this philosophy to be consciously known and steadily improved by raising to the level of consciousness what is held subconsciously in the depths of the psyche."

The aim of the author has been to develop studies in culture to the status of science. He is convinced that social studies can be made scientific and that the social scientists have thus far been misled in their understanding of the scientific method.

A Surgeon's Domain. By Bertram M. Bernheim, M.D., Associate Professor of Surgery, The Johns Hopkins Medical School, Baltimore. Cloth. Price, $3. Pp. 253. W. W. Norton & Co., Inc., 101 Fifth Ave., New York 3, 1947.

Dr. Bernheim has the certificate of competent writing for the public that acceptance by the *Saturday Evening Post* verifies. Two of the chapters in this book appeared in that periodical; the success of those chapters caused him to undertake the larger work. He feels the need of some change for better distribution of physicians and more adequate returns for the young men who undergo the long apprenticeship necessary for surgery. He accuses medicine of having a high concept of scientific needs with a low concept of social needs. Unfortunately for Dr. Bernheim, it does not appear that he has during his long career participated greatly in the activities of medical organizations, nor is he apparently aware of much of the available evidence on some of the points he discusses. Had he been less the arm chair philosopher and more the active participant in the agencies on which rests the responsibility for working out medicine's social relationships, he might be considered in a better position to criticize as he does.

Social Work Year Book 1947: A Description of Organized Activities in Social Work and in Related Fields. Editor: Russell H. Kurtz. Ninth issue. Cloth. Price, $3.50. Pp. 714. Russell Sage Foundation, 130 E. 22d St., New York 10, 1947.

This volume includes two parts. The first consists of 79 articles written by selected authors on various aspects of social work. Of special interest to the medical profession is the statement on medical care by Dean Clark, which is a considerable condensation of the subject largely reflecting the author's personal views. The article on public health comes from Dr. Wilson G. Smillie and is essentially a brief report on subjects of general interest in public health during the past year. Mr. Altmeyer himself contributes the article on social insurance. He is very much in favor of an overall insurance system, including protection against all common economic hazards from the cradle to the grave.

The second half of the book offers a directory of agencies of all types. One must go through the pages carefully to realize what a tremendous number of federal government agencies there are in the field of social welfare. Next come the voluntary agencies. According to the statement in the book, the National Tuberculosis Association has only a little over 3,000 members and yet there are 2,900 affiliated associations. It would be desirable to work out a questionnaire form for the national volunteer agencies which would reflect each of them more adequately in this directory.

Parenteral Alimentation in Surgery with Special Reference to Proteins and Amino Acids. By Robert Elman, M.D., Associate Professor of Clinical Surgery, Washington University School of Medicine, St. Louis, Missouri. Cloth. Price, $4.50. Pp. 284, with 31 illustrations. Paul B. Hoeber, Inc., 49 E. Thirty-Third St., New York 16, 1947.

This treatise, written by one of the leading investigators in the field, was awarded the Samuel D. Gross Prize for 1945. In the first chapter, a historical survey, one finds many interesting facts. The first intravenous injection of fluids was carried out experimentally in a dog by Sir Christopher Wren. Rudolph Matas of New Orleans in 1891 described 20 cases in which he injected 500 to 1,500 cc. of saline solution intravenously when there was considerable loss of blood. The second chapter deals with general indications for parenteral administration of fluids. Then follow chapters devoted to water and electrolyte, energy, vitamin, protein needs, clinical manifestations of protein deficiency, methods of parenteral protein administration, i. e. plasma, amino acids, hydrolyzed protein, practical parenteral alimentation, clinical results with parenteral alimentation—eleven chapters in all. It is not possible in limited space to discuss in detail a book of this type. A number of positive statements are made concerning questions that are still controversial. Suffice it to state that the author, writing in a clear, concise manner has admirably reviewed the pertinent literature in the field, combines experimental and clinical aspects in his discussions and offers practical suggestions for the clinical application of parenteral nutrition in a wide variety of conditions where such support is indicated. It is a unique work combining a detailed review, authoritative information based on the extensive personal studies of the author and an excellent bibliography. The book should be in every hospital library as well as among the current additions to the personal libraries of clinicians, who will want to consult it frequently.

Aérosols médicamenteux: Technique—physiologie—thérapeutique. Par L. Dautrebande. Paper. Pp. 207, with 63 illustrations. J. Duculot Gembloux, Belgium; Masson & Cie, 120 Boulevard Saint-Germain, Paris 6ᵉ, 1946.

This monograph is interesting in view of the increasing use in this and other countries of the "aerosol technic" for treating certain acute and chronic infections of the respiratory tract with nebulized penicillin, streptomycin and sulfonamides. The author, however, refers only to a few studies covering this application of the "aerosol technic" but includes some twenty years' experience with (*a*) the development of apparatus for the production of aerosols, (*b*) the conditions which effect the concentration, settling and physical state of liquid aerosols, (*c*) the local and general action of certain drugs in animals and man when inhaled as aerosols and (*d*) the application of the "aerosol technic" in the treatment of asthmatic conditions with bronchodilator drugs. The author reviews the literature covering other studies in which the "aerosol technic" has been employed. These include (*a*) immunizing against certain respiratory tract pathogens, (*b*) giving of insulin, (*c*) producing experimental airborne infections and (*d*) controlling them with germicidal aerosols and vapors, and (*e*) as a means of studying the pharmacodynamic action of a wide variety of drugs, when inhaled in the nebulized form, on the respiratory tract and other body organs. A long bibliography is included.

Henry Sewall: Physiologist and Physician. By Gerald B. Webb and Desmond Powell. Cloth. Price, $2.75. Pp. 191, with 15 illustrations. Johns Hopkins Press, Baltimore 18, Maryland; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

This book is an excellent account of the life and work of Henry Sewall. The first chapter, entitled "Inheritance," deals with his ancestry. This is followed by a chapter pertaining to his youth and another to his college days. His attendance and activities in medical school and studies abroad are described in chapters four and five. A full chapter is devoted to Dr. Sewall as a physiologist, from the time he became professor of physiology at the University of Michigan in 1882. Here he conducted the famous studies on rattlesnake venom.

Beginning in 1884 Dr. Sewall had at least annual attacks of bronchial or pulmonary illness. In the spring of 1886 he went to Denver to recuperate but returned to Michigan the next October. His health again failed, and he was granted a leave of absence, and the University of Michigan conferred on him the unusual degree of honorary Doctor of Medicine. He and Mrs. Sewall returned to Colorado in 1888, where they spent the remainder of their lives. Here Dr. Sewall became internationally known as a physician. He began practicing in Denver in 1891 and resided there until his death in 1936. His numerous scientific accomplishments are related in this book, and it is pointed out how he used his home as a laboratory until the National Jewish Sanatorium provided him space. Thereafter he was most appreciative of all the modern facilities made available for his investigations.

Dr. Sewall's complete bibliography is included. His first paper appeared in 1878. Every year thereafter he published one or more papers, except 1889, until his death in 1936.

Dr. Webb, who was a fellow practitioner with Dr. Sewall for many years, has demonstrated on many occasions his wide knowledge of the history of medicine. Into this volume he and Mr. Powell, while presenting Dr. Sewall's activities and accomplishments, have woven rare and interesting contemporaneous historical events. This book is written in such a delightful style that physicians will find it both entertaining and instructive.

Black Anger. By Wulf Sachs. Cloth. Price, $3. Pp. 324, with 1 illustration. Little, Brown & Co., 34 Beacon St., Boston 6, 1947.

The author is a South African psychoanalyst who has written many works in his field and who has been concerned particularly with psychoanalytic studies. He is a member of the British and International Psychoanalytic Societies and may therefore be considered fully qualified in his field. The present book should interest the general readers as well as those who are especially concerned with psychiatry. The book is the true story of a native African medicine man approached from the point of view of the psychoanalyst who presents not only the life experiences of the subject but also his inner conflicts. The primitive society from which the medicine man emanated had developed its own psychologic treatments. The volume gives an interesting picture of the life of South African natives and the difficulties in adjustment of their culture to that of the white civilization in which they live.

Devil by the Tail: A Novel. By Langston Moffett. Cloth. Price, $3. Pp. 431. J. B. Lippincott Company, 227 S. 6th St., Philadelphia 5, 1947.

This is another story about alcoholism, summarized also from both the medical and the psychiatric point of view by the words opposite the contents page: "The characters and situations in this work are wholly fictional and imaginary and are not intended to portray any actual persons or groups of persons."

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

RECURRENT PNEUMONIA

To the Editor:—A white woman aged 68 has had recurrent fever for eight weeks. Radical amputation of the right breast was performed three years ago for carcinoma. About eight weeks ago she began to have a fever which varied from normal in the morning to 102 F. in the evening. Physical examination disclosed that she was emaciated and pale. There were no other definite physical findings. X-ray examination of the chest showed an atypical pneumonia of the lower left lobe. Penicillin in adequate doses had no effect. The pneumonia gradually resolved, and the patient was afebrile for about one and one-half weeks. She again became febrile and another x-ray of the chest disclosed another atypical pneumonia in the same location. Penicillin, sulfadiazine and streptomycin were all tried without apparent benefit. Serial x-rays of the chest showed complete resolution of the pneumonic process. The patient has continued to have a recurrent fever since that time, the temperature remaining normal for eight to twelve days, then beginning to rise in the evenings to 101 to 102 F. for eight to twelve days. Since the beginning of the present illness the patient has had a moderately severe anemia, the average blood picture being hemoglobin 65 to 70 per cent, erythrocytes 3 to 3½ million, leukocytes 8 to 14 thousand; the differential count was normal. Bone marrow studies are negative. Liver function tests have been normal, including galactose tolerance, icterus index, van den Bergh, prothrombin time and urobilinogen. Urinalysis has been negative. The blood Wassermann reaction is negative. Agglutination tests for typhoid, paratyphoid and undulant fever have been negative. Blood culture has been sterile. Blood chemistry tests are also negative. Complete gastrointestinal series and gallbladder x-ray studies have given normal results, as well as x-rays of the long bones. In addition to the antibiotics the patient has received repeated blood transfusions, liver extract every two days parenterally, Lextron ferrous capsules and vitamin B complex. She has become progressively worse despite treatment.

A. J. Edelstein, M.D., Johnstown, Pa.

Answer.—Recurrent pneumonias, especially in the same area, in a patient of 68 suggests partial obstruction from a number of causes, the chief of which is a primary or metastatic neoplasm. Viral pneumonia may relapse but is seldom followed by febrile attacks for two months. Tuberculosis, foreign body, bronchial stenosis and other causes must also be considered. Mention is not made of cough or of sputum, which might suggest bronchiectasis with recurrent peripneumonitis. In the case described in the query, metastatic neoplasm seems most likely, particularly after a mastectomy for carcinoma. Metastasis to the lung or pleura is common. Unrelated primary bronchogenic carcinoma is also possible. Further attempts at diagnosis should include bronchoscopy and aspiration of exudate to search for tumor cells after the method of Herbut (*M. Clin. North America* November 1946, p. 1384) and/or bronchography with iodized oil. If a neoplasm is present, other treatment is not indicated except that of the supportive type already used.

ELECTROCAUTERY

To the Editor:—Please give the following information concerning the new Cameron Cauterodyne (Model M for ear, nose and throat use): 1. Can it be used in general ether anesthesia? 2. When used in tonsillectomy is the occurrence of secondary hemorrhages greatly reduced over the ordinary surgical removal? 3. What is the difference between the use of the dehydrating current and the desiccating current? 4. What is the consensus as to its use for daily office practice?

R. A. Quisling, M.D., Madison, Wis.

Answer.—1. There is a definite risk of explosion which does not permit the use of apparatus of this kind during the course of a general ether anesthesia. This is especially true if the operation is to be about the mouth, as in tonsillectomy.

2. Secondary hemorrhage is not reduced by comparison with its occurrence after ordinary surgical removal. It may not be any more frequent, but it is apt to come later and may be more stubborn than after surgical removal.

3. The difference between dehydrating and desiccating currents is more academic than practical. In the type of procedure under discussion, water is abstracted from the tissues. When the effect is superficial, one speaks of desiccation; when it is somewhat deeper, one can speak of a dehydrating effect, and the last and most destructive is the coagulating effect.

4. It is not easy to poll doctors who use this particular model. Its circuits have been accepted by the Council on Physical Medicine of the American Medical Association, and there is every reason to believe that it is a reliable piece of apparatus. For strictly office use, not involving more ambitious operations, the same company has smaller models which are adequate.

TREATMENT OF TRENCH FOOT

To the Editor:—What treatment is recommended for the residuals of trench feet? These patients, veterans of the European Theater of Operations, complain chiefly of increased sensitivity to cold, increased sweating, callous formation and occasional pain, tingling and numbness. Physical findings are usually minimal–mild color changes and slightly lowered skin temperature with little or no change in the peripheral pulse.

M.D., Iowa.

Answer.—The late changes in trench foot can be readily divided into two groups: In the first, one can demonstrate excessive sympathetic activity as manifested by coldness, cyanosis, hyperhidrosis with desquamation of the epithelium and bromidrosis. Sympathetic block with procaine hydrochloride relieves these symptoms, sometimes permanently, more often just for a few hours or days. If the result of procaine block is evanescent, lumbar sympathectomy is indicated and has been successful in eliminating the vasomotor symptoms and the excessive sweating, with its consecutive blistering and bad odor. Unfortunately only about a fourth of patients belong to this group. The majority show peripheral nerve involvement, mostly of the plantar nerves, which result in pain on weight bearing, numbness and burning of the sole of the foot and toes, and intolerance to heat or friction. While anesthesia is rarely present, the areas complained of are either hypoesthetic or hyperesthetic. In this group one may also see stiffness of the toes, hyperkeratosis and other trophic changes which signify the severity of exposure and which are fundamentally due to the clotting of the plasma in the extravascular spaces and to increased capillary permeability. Treatment in this group has not been too satisfactory. Walking, swimming or bicycle riding increase the patient's confidence. Massage and whirlpool baths may give some benefit. Rubber heels or thick pieces of leather placed in front of the heel to shift the pressure from the painful metatarsal heads are helpful. However, this dysesthesia of the foot may last a long time and has not disappeared for years after the initial exposure. Obviously many patients show a mixture of the two syndromes. In these the preponderance of one or the other variety should direct treatment. It must be stated, however, that sympathetic denervation not only does not relieve the peripheral neuropathy but may aggravate the symptoms. That some of these patients suffer from a psychoneurosis is an additional warning against surgical procedures except in the clearcut vasospastic group in mentally stable persons.

REACTIONS TO UROGRAPHIC MEDIUMS

To the Editor:—What is the incidence of reactions following the intravenous injection of opaque substances for urographic study? What is the incidence of fatalities? Is it current practice to do a preliminary sensitivity test with the radiopaque substance to be used? If not, should this be done?

M.D., New York.

Answer.—Several cases have been reported in which a severe reaction followed the intravenous injection of opaque mediums currently employed in urography. It would be difficult to obtain exact figures on the incidence of such reactions.

The mediums most frequently employed at present are Neo-Iopax (disodium methyl-diiodo-chelidamate) and Diodrast (diiodopyridone acetic acid diethanolamine). Mild reactions immediately following the injection of either of these mediums occur frequently. As a rule they consist only of a feeling of intense heat, pain localized to the area of injection or nausea, which usually pass away in a few seconds. In about 5 per cent of cases such reactions become quite severe and occasionally may be accompanied with temporary prostration. If the substance is injected into the tissues outside a vein, the pain may be severe and persistent. Venous thrombosis also has been reported, which usually is localized to the vein injected.

Although fatality following injection of these mediums is infrequent, a number of such cases have been described and they probably occur more frequently than has been reported. On the other hand, in a series of more than 25,000 excretory urograms made with Neo-Iopax in recent years at the Mayo Clinic, only one fatality has been reported. A postmortem examination was not obtained in this case, but judging from the symptoms, death apparently was due to acute toxemia. It was found later that there had been a severe reaction following a previous urogram.

A routine test for sensitivity to iodine before injecting urographic mediums has been recommended. However, the rarity of fatal accidents and the difficulty of knowing whether such a test necessarily indicates a toxic reaction would make one question the advisability of its routine employment. Needless to say, care should be taken in the selection of the patients. It is questionable whether excretory urography should be employed in patients who are greatly debilitated from any cause or in those who are known to be allergic to iodine preparations.

CYANIDE POISONING FROM INDUSTRIAL SOURCES

To the Editor:—A mining company uses cyanide in processing its ore. There is a possibility that at some time traces of cyanide may pass through the tailings and enter the stream below the camp. What concentration of cyanide (mostly as sodium salt) would render this water unsafe for drinking purposes and be apt to kill fish in this stream? The stream flows over several small waterfalls and over rock for nearly 10 miles before coming to the next settlement. It requires a minimum of four to five hours to reach this village. The rock is mostly limestone. Would much of the cyanide remain under these circumstances? What symptoms might be expected to develop from prolonged ingestion of minute quantities of cyanide?

Theodore Gallup, M.D., Holden, Wash.

ANSWER.—The frequency of poisoning from cyanides from industrial applications and waste products therefrom is surprisingly low in the light of the injurious properties of hydrocyanic acid and cyanides. Thousands of gallons of concentrated cyanide solutions from plating vats are dumped into the public sewers in every city without known subsequent damage to sewer workers or others. Spent materials from cyanide metal hardening furnaces are handled by the ton with almost complete disregard for potential injury. With the cyanide flotation method for metal concentration the average application of cyanide salts approximates 3 pounds per ton of water or ore. Since the average flotation mill concentrates approximately 100 tons of ore daily, the effluent water represents a content of some 300 pounds of cyanide. Slightly more than 53 per cent of sodium cyanide is made up of the cyanogen constituent; thus some large quantity such as 159 pounds of cyanogen daily may be brought in contact with the water effluent ultimately to be discharged into some stream. The rarity of poisoning from industrial application of cyanides (hydrocyanic fumigation excepted) is in part attributable to the facility with which cyanides are transformed to carbonates or other harmless compounds. In cyanide flotation work, even the fairly common dermatitis is more often attributable to commercially employed alkalis than to cyanides.

The maximum therapeutic dose of sodium cyanide is ½ grain (32 mg.) daily administered orally and intermittently. This represents approximately 16 mg. of cyanogen. Four times this quantity from a single intake has produced fatality in man. An atmosphere containing 0.2208 mg. of hydrocyanic acid per liter of air is tolerable for prolonged exposure. If a person breathes 6 cubic meters of air per day, the total intake of hydrocyanic acid would approximate 132 mg., although perhaps not more than one fourth, or 33 mg., might be retained in the body. It is probable that 10 mg. of cyanogen is near the daily maximum that can be tolerated by the body without demonstrable injury. In the instance described in the query it would be desirable to establish the fact that the daily intake of water does not provide a greater intake of cyanogen than 10 mg.

The situation may be different for fish life. It is not necessary to estimate the quantity of cyanogen that will destroy adult fish but only the quantity that will upset the normal piscatorial economy. Quantities of cyanogen possibly harmless to adult fish may inhibit the hatching of roe or kill off certain of the lower aquatic life forms essential to fish economy. Concentrations of cyanogen on the order of 0.0027 per cent may inhibit the hatching of certain aquatic life eggs and may kill protozoa. Therefore the peril to fish life may be greater than for human life.

It is almost certain that the usual content of cyanide from a flotation mill will have disappeared in any sizable stream after a flow of 10 miles with great water turbulence from waterfalls, and after an elapsed travel time of four or five hours. However, unusual circumstances such as the presence of agents that inhibit oxidation of cyanides or the fortuitous presence of acid may upset these calculations. Should actual damage arise, this will be shown in mild cases by vertigo, headaches, dyspnea, nausea, vomiting, salivation and tremors. In some instances in which cyanides from flotation mills have been suspected as a source of injury to human beings inquiry has established that arsenic derived from mineral acids or possibly from ores was the offender rather than cyanides.

UNUSUAL DELAYED REACTION AFTER PENICILLIN IN PENDIL

To the Editor:—A patient developed acute bilateral mastitis ten days after delivery. She was given sulfathiazole and 100,000 units of penicillin in 3 cc. of Pendil twice daily intramuscularly in the deltoid muscles. The injections were discontinued after four days, as the inflammation had apparently disappeared. One week later the mastitis recurred in the left breast and two days later in the right breast, accompanied with high fever and chills. The patient was again given penicillin in the same dosage and in the same area. After five days the dosage was increased to 200,000 units per dose in 3 cc. of Pendil. More definite improvement followed, and at the end of ten days of treatment all signs of inflammation were gone. The penicillin was continued for four more days, making a total of fourteen days' treatment for the recurrent mastitis. There was no recurrence. About four weeks after completion of treatment the patient noticed large indurated areas over both deltoid areas. At times a large inflamed area would develop, last a few hours and then fade out. Several have remained red and at times become a dark purplish. The indurated areas have now gravitated downward in one place to a point about 2 inches below the elbow. They extend to all surfaces of the arm. In places a hard area 1 to 3 cm. in diameter and several inches long can be palpated. Considerable discomfort is present most of the time, especially at night. Hot saline applications and Benadryl 50 mg. four times daily have not had any appreciable effect. Has the Pendil (oil) not been absorbed and is this an allergic reaction? Any recommendations as to treatment will be appreciated. What is the prognosis?

M.D., Texas.

ANSWER.—This is a most unusual delayed type of reaction. It probably represents hypersensitivity to one of the agents injected into the areas. Such a delayed reaction is probably not caused by penicillin. Pendil, as then marketed, is a combination of peanut oil and a cholesterol derivative. There is a possibility that the inflammatory reaction with hemorrhage is associated with the retention of this mixture in the tissues, and the acquired sensitivity is due to peanut oil. Since the reaction is unusual, a definite statement concerning prognosis cannot be offered. It is quite likely that the sites of reaction will show fibrosis eventually. Treatment should be directed to alleviating any local discomfort.

STREPTOMYCIN FOR CHRONIC PYURIA

To the Editor:—Would you please venture an opinion, comment and give a prognosis or suggestion in the following hypothetical case? A man aged 50 had either a pyelitis or a pyelonephritis two years ago which apparently subsided after two weeks of bed rest and treatment with methenamine and sulfonamide drugs. However, in five months it was found that the urinary tract infection had not cleared up and it has persisted ever since. Two years ago cystoscopy was done and a retrograde pyelogram made by a competent urologist. Repeated urine cultures have shown Escherichia coli and Streptococcus fecalis. He has received extensive treatment with sulfonamide compounds and penicillin. He is now receiving mandelic acid therapy. About nine months ago the patient started to have anginal pains on effort. He later developed a coronary thrombosis and has been bedfast for the past six months. He is relieved by glycery trinitrate 1/100 grain (0.65 mg.) and erythrol tetranitrate 1/6 grain (11 mg.) after each meal. Streptomycin therapy is contemplated. Please suggest the dosage of streptomycin.

M.D., Kansas.

ANSWER.—Cystoscopy and retrograde pyelograms are indicated if the patient's condition will tolerate the procedure. This is important since streptomycin and other urinary antiseptics are ineffectual in the presence of urostasis or calculous disease. One or both of these states usually exists in the presence of persistent urinary infection. Recent literature suggests that susceptible bacteria rapidly lose their susceptibility to streptomycin. For this reason not less than 3 million units should be given during each of the first three days. This should be followed by 1 Gm. daily for an additional four days. Alkalization of the urine will enhance the effect of the streptomycin. Mandelic acid should be given consecutively with the urinary p_H established at 5.5 or lower because it is probably the best antiseptic for Streptococcus fecalis.

TREATMENT OF POSTPROSTATECTOMY PYURIA

To the Editor:—Please discuss the treatment of pyuria due to Bacillus coli infection after transurethral operations with special reference to sulfathiazole, sulfadiazine and sulfamid. What other methods are there to reduce pyuria?

Samuel Rosenstein, M.D., San Antonio, Texas.

ANSWER.—The consensus seems to be that sulfadiazine and sulfathiazole are more efficacious than sulfamid. However, streptomycin is superior to these three sulfonamides. The important point in any patient with a persistent pyuria is the recognition of an associated pathologic condition that may be present and be the underlying cause. For instance, after a transurethral resection, residual urine may still be present, or there may be an infection in the prostatic bed. A study of the upper urinary system also should be made. This might reveal a hydronephrosis, "silent" renal stones or other pathologic findings.

THE ETIOLOGY OF INFECTIOUS HEPATITIS

W. PAUL HAVENS Jr., M.D.
Philadelphia

The modern concept of the virus etiology of infectious hepatitis is a product of the investigations of recent war years both abroad and in this country. This theory is in accord with at least three facts: (1) the consistent failure to identify any causative bacteria with this disease;[1] (2) the production of hepatitis in human volunteers by the administration of a filtrable agent,[2] and (3) the development in patients in the early stages of this disease of leukopenia (with lymphopenia and subsequent neutropenia) similar to that found in several other virus infections.[3]

Historically, infectious hepatitis is an old disease and one which has been long known in civilian and military life. Epidemics of what may probably be regarded as this disease were recorded during Napoleon's campaign in Africa and in the Civil War in this country, the Boer War in South Africa and in World Wars I and II. During World War I considerable effort was made to demonstrate an etiologic association between various strains of salmonellae and infectious hepatitis. It is now apparent that such an association probably represented the simultaneous occurrence of two diseases whose manner of spread, namely, the intestinal-oral route, was the same.[1] In addition the recognition of spirochetal jaundice and of its causative agent Leptospira icterohemorrhagiae[4] caused confusion, in that for many years the investigations of outbreaks of infectious jaundice were carried out largely with the concept of leptospiral etiology. Blumer[5] was among the first in this country to indicate that infectious hepatitis probably represented the epidemic form of catarrhal jaundice. It is only recently that this idea has been more widely accepted.

Infectious hepatitis may appear either sporadically or in large or small epidemics. Family outbreaks are not uncommon. In civilian life it is said to be primarily a disease of childhood, although its capacity to attack the young adult is attested by the magnitude of military epidemics. Clinically the disease is similar, as it appears in children and adults, although its course on the average is much severer in the latter group.

During the late war tens of thousands of cases of this disease occurred among troops in various parts of the world, and excellent clinical descriptions have been recorded. In addition considerable knowledge has accumulated concerning treatment and the use of certain tests of liver function in diagnosis and prognosis.[6] In the accompanying chart is described the course of disease of an adult patient with infectious hepatitis.

ETIOLOGIC AGENT

Actually little is known in regard to the etiologic agent. The lack of susceptible laboratory animals or adequate serologic tests, as well as failure to propagate the agent in embryonating eggs or tissue culture have made the problems more difficult. Up to the present the best source of information has been in the use of human volunteers, to whom it is possible to transmit the disease readily. In this manner certain facts have become known about the etiologic agent, the possible manner of spread of virus and the prevention of the disease. A few strains of infectious hepatitis virus have been obtained from different parts of the world, and the patterns of their behavior in man have been compared.

Numerous attempts to transmit the virus of infectious hepatitis to the common laboratory animals, including many rodents, many species of monkeys and even chimpanzees have failed.[7] Successful transmission of virus to pigs,[8] canaries[9] and embryonating eggs[10] has been

reported but not confirmed. More recently MacCallum and Miles[11] have described the transmission to rats of a filtrable icterogenic agent, following the administration of material derived from patients with infectious hepatitis. It is impossible as yet to know whether this agent originated in the patients or represents a spontaneously occurring infection in the rat. The spontaneous appearance of a filtrable agent causing hepatitis has already been observed in colonies of supposedly healthy mice.[12]

German workers[13] have recently reported the virus of infectious hepatitis as being a polyhedral body with a diameter of the order of 180 millimicrons when visualized by means of the electron microscope. Neither this agent nor the rodent agent have been described as having reproduced the disease in human volunteers.

TRANSMISSION EXPERIMENTS IN HUMAN VOLUNTEERS

A large part of the available information about hepatitis has been obtained through the use of human volunteers in the experimental transmission of this disease. Such experiments of necessity employ a relatively small number of subjects, thereby limiting the statistical value of results. It is evident that positive results are of value and the negative ones less so, requiring considerable caution in their interpretation.

Clinical course of volunteer with experimentally induced infectious hepatitis. The arrow indicates the time of inoculation. Rectal temperatures are recorded. Five milligrams of sulfobromophthalein sodium ("bromsulphalein") per kilogram of body weight was injected intravenously, and the percentage retained in the blood was measured after thirty minutes.

It is pertinent to call attention at this time to the arbitrary distinction which has been made between the naturally occurring disease, infectious hepatitis, and homologous serum jaundice. This latter term has been reserved for the form of hepatitis produced in persons who have been artificially infected through the parenteral inoculation of human blood products in the form of vaccines, convalescent serums or transfusions of blood or plasma.[14] Although the exact relationship between these two artificially separate forms of hepatitis is not clearly understood, it would seem likely that they belong to the same general group. The question has naturally been raised whether all serum jaundice is not the artificial production of infectious hepatitis. The solution of this problem is not yet known, although experiments in the transmission of both forms of hepatitis to human volunteers have elicited certain information. In the accompanying table is recorded a comparison of two strains of virus, that of infectious hepatitis[15] and that of homologous serum jaundice,[16] employed in such experiments in the laboratory of the Neurotropic Virus Disease Commission during the past two years. It is not yet determined whether the differences in route of inoculation, length of incubation period, distribution of virus, period of infectivity and lack of cross immunity are representative of the activities of actually different viruses or of antigenic differences of various strains of one virus.

The etiologic agent of infectious hepatitis is known to be filtrable through bacteria-tight filters, resistant to a temperature of 56 C. for at least thirty minutes and able to withstand chlorination (1 part chlorine residual per million).[17] It is readily recovered from the blood or feces of patients in the acute, preicteric or early icteric phases of disease. Several attempts to detect virus in the urine or nasopharyngeal washings of patients at similar periods have had contradictory results, although in general they have been unsuccessful.[18] The period of infectivity[19] of patients with this disease has been investigated to determine when virus appears in the blood and feces and how long it remains there. A single attempt to recover it from the blood midway through the incubation period of 1 experimentally infected human volunteer was unsuccessful, but it has been found in the blood three days before the onset of disease.[17c] Attempts to recover virus from the blood and feces in the convalescent period as early as one month after onset of disease have been unsuccessful. The possibility of a carrier state or whether patients with relapse have virus in their blood or feces has not been determined.

The natural manner of transmission of infectious hepatitis is not completely known, although epidemics carried by water,[17b] food[20] and milk[21] have been described. Experimentally, there is evidence that the intestinal-oral route may be of importance. This is based on the fact that the disease may be transmitted to human volunteers by feeding them infectious feces or serum.[22] Some support for this concept is also furnished by the observation that infectious hepatitis often flourishes in places where sanitation is poor and where other diseases spread by the intestinal-oral route (bacilliary dysentery and salmonellosis) are prevalent.

It is difficult to evaluate the immune response elicited by the virus of infectious hepatitis, but there are certain epidemiologic and experimental data which suggest that protective substances may be elaborated in man following infection. Second attacks of infectious hepatitis are said to be uncommon. Experimentally, immunity has been demonstrated in human volunteers convalescent from hepatitis caused by two different strains of virus when challenged with the homologous strain six to nine months after their initial infection.[23] Partial cross immunity between these two strains of virus has also been shown in that volunteers who were convalescent from infection caused by a strain of virus obtained from children with the disease in Pennsylvania [24] were immune when inoculated with a strain of virus derived from a soldier who contracted infectious hepatitis in Sicily.[22b] Further evidence has also been furnished by the demonstration of the prophylactic value of human gamma globulin when administered in the incubation period of infectious hepatitis.[25] This implies the presence of specific antibodies in the blood of the healthy human adult population of this country, possibly elicited by previous clinical or subclinical infection.

Comparison of Behavior of Viruses of Infectious Hepatitis and Homologous Serum Jaundice in Experimentally Infected Human Volunteers

	Virus	Infectious Hepatitis [15]	Homologous Serum Jaundice [16]
1	Filtrable	Seitz EK	Seitz EK
2	Resistance to heat	56 C, 30 minutes	56 C 60 minutes
3	Susceptible animal	Man only	Man only
4	Incubation period (days)	15 to 34	56 to 134
5	Route of infection (experimental)	Parenteral or oral inoculation	Parenteral inoculation
6	Virus in stool	Acute phase	Not demonstrated
7	Virus in serum	Acute phase	Incubation period and acute phase
8	Immunity		
	A. Homologous	Present	Not tested
	B Heterologous	Not tested	None apparent

SUMMARY

It is evident that a better concept of infectious hepatitis as a disease entity has been established as a result of clinical and experimental data accumulated during recent war years. In addition to the clarification of certain clinical aspects this disease has been classified as one of virus etiology, which may be spread by the intestinal-oral route and prevented by passive immunization. Although the exact relationship of this disease to another form of hepatitis arbitrarily designated as homologous serum jaundice is not defined, it would seem likely that the two are closely related although not identical, and belong in the same general group.

THE PATHOLOGY OF EPIDEMIC HEPATITIS

LIEUTENANT COLONEL TRACY B MALLORY
Medical Corps, Army of the United States

In the present state of knowledge of epidemic hepatitis, this disease can be defined only in descriptive terms, since the infectious agent has not yet been isolated and identified. The disease is transmissible to human beings by oral or parenteral inoculation with a filter-passing agent, presumably a virus,[1] but in contrast to spirochetal jaundice and yellow fever experimental infection of animals has never been accomplished. It is characterized clinically by evidence of hepatic dysfunction and pathologically by inflammatory and degenerative changes in the hepatic parenchyma. It ordinarily runs a benign, self-limited course of two to three weeks' duration, but symptoms may persist for months, with or without acute recrudescences. Although the mortality is low, death may occur at any stage. On clinical and pathologic grounds it is indistinguishable from the endemic, sporadic disease known for many years as catarrhal jaundice, from homologous serum jaundice and from at least certain cases of hepatitis attributed to arsphenamine therapy.

HISTORICAL DATA

The literature of epidemic hepatitis has recently been reviewed by Lucké,[2] and nothing would be gained by extensive repetition at this time, but a brief historical résumé will serve to explain why the pathology of the disease was comparatively unknown until the outbreak of the second world war. Jaundice due to massive necrosis of the liver was recognized as early as 1842 by Rokitansky,[3] who first described and named acute yellow atrophy.[4] It was, however, regarded as a uniformly fatal disease. Twenty-three years later Virchow [5] suggested that the benign, transient form of jaundice usually seen in young persons was due to a catarrhal inflammation, which occluded the papilla of Vater with a mucous plug. He proposed the term "Icterus catarrhalis," which quickly won worldwide acceptance and dominated medical thought for three

3. Rokitansky, C.: Lehrbuch der pathologischen Anatomie, Vienna, W. Braumuller, 1861, vol. 3, p. 269.

4. It should be emphasized that the term "acute yellow atrophy" has no specific connotation but merely means any acute massive form of hepatic necrosis, which may be caused by a variety of factors. The acute yellow atrophy found in epidemic hepatitis corresponds to the kind formerly known as idiopathic.

5. Virchow, R.: Ueber das Vorkommen und den Nachweiss des hepatogenen, insbesondere des katarrhalischen Icterus, Virchows Arch. f. path. Anat. **32:** 117, 1865.

generations. Few people considered the possibility that the two diseases might be related. Probably the first to do so was Flindt,[6] who as early as 1890 assembled epidemiologic *evidence linking the sporadic and epidemic* forms of the disease and showing that both could terminate in an acute form of atrophy of the liver. He concluded that the essential lesion was a degeneration of the hepatic parenchyma rather than a disease of the extrahepatic biliary ducts. Unfortunately his work was published in an obscure Danish journal and was quickly forgotten even by his compatriots. In 1912 Cockayne[7] independently reached the same conclusion and abundant confirmation followed, particularly from the Scandinavians, Linstedt,[8] Ehrstrom[9] and Wallgren,[10] all of whom pointed out the parallelism between the incidence of hepatitis and deaths from atrophy of the liver. Despite this steadily increasing volume of evidence general medical opinion remained comparatively uninfluenced, and as late as 1930 Bergstrand[11] reported from Stockholm an epidemic of "yellow atrophy of the liver," paying scant attention to the concurrent epidemic of hepatitis in southern Sweden.

Though the evidence was by now clear that patients dying of hepatitis regularly showed massive necrosis of the liver the possibility remained that this was a superimposed, merely terminal complication. The first *evidence of hepatocellular degeneration in early stages* of the disease was provided by Eppinger.[12] During the first world war he observed 4 cases of hepatitis in wounded soldiers who died of tetanus rather than of hepatic insufficiency. In all these cases the major biliary ducts were unobstructed and free of inflammation, though such extensive degenerative changes in the liver cells were present that he likened them to a *miniature form of acute yellow atrophy.* Convincing evidence of hepatic involvement in all stages of the *disease could only be provided by biopsy material.* Such reports were at first sporadic and concerned individual and clinically atypical cases in which doubt in regard to diagnosis had led to surgical exploration of the patient (Klemperer, Killian and Heyd[13] and Schrumpf[14]). The development in 1939 by Roholm and Iversen[15] of a technic for aspiration biopsy of the liver permitted for the first time systematic studies of groups of patients. Their method was quickly adopted in other countries, and Dible, McMichael and Sherlock[16] in England and Axenfeld and Brass[17] in Germany utilized it with equal success. All these groups of investigators demonstrated a combination of inflammatory and degenerative changes in the liver throughout the icteric period of the disease.

MATERIAL

The epidemic of hepatitis in the American Army during the recent war has furnished abundant opportunity for further studies of its pathologic aspects. These have been or will be published in detail in other places.[18] Since I had the privilege of collaborating in several phases of the work I will quote liberally from these observations in this article. From the spring of 1942 to April 1945 material from 296 fatal cases of the disease was submitted to the Army Institute of Pathology. The first 118 of these were reported by Lucké[2] in 1943. The succeeding 178 were reviewed by Lucké and Mallory.[18b] During the autumn of 1944 and the winter and spring of 1945 a series of 160 peritoneoscopic biopsies of the liver were collected by Horan, Jolliffe and Mallory[18c] from 137 volunteers exemplifying various stages of the disease. All were procured in Italy at a time when hepatitis was epidemic in the area. There were no untoward complications of the procedure, and the patients either returned to duty or were sent back as convalescents to the United States. Consequently they may be regarded as rep*resentative of the nonfatal form of the disease.* Since the observations differ significantly it will be best to *consider the pathologic data of the fatal and nonfatal* cases separately.

FATAL HEPATITIS

Most cases of fatal hepatitis can readily be classified *into one of two types, subacute and fulminant, which* show corresponding variations in clinical and pathologic *observations. The first, or subacute, type is exemplified* by the Swedish epidemic of 1927 reported by Bergstrand[11] *and by the series of cases from the American* Army during 1942 and early 1943 which have been reported by Lucké. None of the patients in the latter group died in less than ten days A few survived one hundred days or more, and in 59 per cent the duration ranged from twenty to fifty days. In these cases the livers showed extensive but irregularly distributed necrosis and numerous foci of regeneration. In the material studied by Lucké and myself at the Army Institute of Pathology since August 1943 the *majority (53 per cent) of the patients died in less than* ten days, many in as short a period as three or four days and a few even before the onset of jaundice. In this type of case necrosis is diffuse and massive and no evidence of regeneration is seen.[18b] Cases of this type have recently been reported by Wood[19] in material derived from personnel of the United States Navy. Despite the difference in the two types, enough points of similarity and enough transitional forms are observed *to make it certain that one is dealing not with two* diseases but with a wide range of reaction to the same fundamental disorder.

The significant pathologic process of the disease is centered in the liver. In the subacute form of the disease the organ is grossly deformed. It is usually smaller than normal, commonly weighing 1,000 to 1,400 Gm., but may be as small as 600 Gm. or may even be enlarged, depending on the relative proportions of necrosis and regeneration. The external surface is irregular. Depressed, wrinkled, usually reddish patches alternate with projecting yellow-green nodules or bosses. The fulminant cases, in contrast, show a diffuse and uniform alteration throughout the liver. Frequently the organ is but slightly shrunken; it may be tense but is usually soft and may be so flabby that it tends to flatten when laid on the table. The capsule is often wrinkled. The color is extremely variable, yellow, red or even purple, and often mottled. On cross section the markings may be exaggerated, resembling an extreme form of nutmeg liver or may be totally obscured. In some the congestion is so intense that the cut surface resembles spleen more than it does liver. In most cases one would not suspect from the gross appearance of the organ the massive necrosis of parenchyma which the microscopic sections reveal.

Path. **41:** *345* (April) 1946.

The microscopic appearances of the liver in the two types of the disease differ less than the gross observations would lead one to expect. Common to both, though the proportions vary, are two main features: necrosis of hepatic cells and inflammatory reaction. In neither is there any involvement of the reticulum other than shrinkage in areas where parenchymatous cells have disappeared.

The necrosis is almost invariably central. In the subacute type it is irregular in distribution. It affects some lobules in their entirety, others only partially. In the fulminant type the distribution is more uniform, and only narrow rims of viable liver cells persist at the extreme periphery of the lobules. In both types the necrosis always appears to be of the autolytic rather than the coagulative type, and even in the most acute cases with clinical histories indicating durations of less than three days the affected cells have usually completely disappeared.

The inflammatory reaction is found chiefly in the stroma of the portal areas and at the interlobular boundaries. It is composed predominantly of histiocytes, lymphocytes and plasma cells, but neutrophils and eosinophils are always present in small numbers. Inflammatory reaction within the lobule is inconstant. It is predominantly histiocytic in character, though neutrophilic leukocytes may be present in varying proportions. Sometimes the histiocytes are numerous enough to almost seem to replace the missing liver cells; in other cases they are present in small numbers only. A final evidence of inflammation is endophlebitis of the central and other efferent veins. The periportal and intralobular inflammatory reactions are usually more pronounced in the fulminant than in the subacute cases. The central endophlebitis in contrast is more conspicuous in the cases of longer duration.

Regenerative changes occur both in hepatic cells and in biliary duct epithelium. Changes in the latter are the first to appear, and proliferation of the biliary ducts may already be evident in the most acute cases, even with apparent durations of only two to three days. Conspicuous regeneration of liver cells in contrast appears only after a latent period of several days. It is the lack of significant hepatic cell regeneration which serves to distinguish anatomically the fulminant from the subacute type. When regeneration finally begins it invariably starts from persisting cells at the periphery of the lobule. The newly formed cells are often abnormally large and multinucleate and seldom succeed in reconstituting normal lobules with orientation of the cords about a central vein. In areas in which lobular destruction has been complete regeneration does not occur, accounting for the large depressed foci of "red atrophy" which separate the regenerative nodules of the subacute type.

EXTRAHEPATIC PATHOLOGY

In contrast to the dramatic changes in the liver, little that is noteworthy is found in the remainder of the body and most of what is seen can be explained as secondary to destruction of hepatic parenchyma. The extrahepatic biliary ducts so infrequently show any evidence of occlusion that the occasional presence of a small plug of inspissated material in the common duct or papilla of Vater can be considered coincidental. Lymphoid hyperplasia is frequent, especially in acute cases, and may be generalized or restricted to the abdominal nodes. The spleen is commonly slightly enlarged, from 200 to 300 Gm., and only occasionally reaches the 500 to 600 Gm. range. In the acute cases the enlargement is dependent on congestion and hyperplasia; in those of longer duration it gradually assumes the character seen with portal hypertension. The phlegmonous enteritis frequently noted as a terminal complication of the subacute cases was not observed in the fulminant type. Ascites is common and increases in frequency with chronicity. The kidney in acute cases shows fat storage in the proximal convoluted tubules and in the subacute ones may show a bile nephrosis of moderate severity. Despite the prominence of cerebral symptoms acute cases show only a mild nonspecific encephalopathy. Those of longer duration occasionally show slight lymphocytic infiltration of the meninges and lymphocytic cuffing of small vessels in the basal ganglions. The lesions do not suggest direct virus infection of the central nervous system.

Table 1.—*Histologic Observation in Acute Phase of Hepatitis*

		Histopathologic Changes		
Group	Number	Positive	Doubtful	Negative

Subicteric	7	5	1	1
Nonicteric . . .	18	5	5	8

NONFATAL HEPATITIS

Epidemic hepatitis is characteristically a benign disease, since at least 99.6 per cent of all patients recover. The fatal case is atypical, so it is only by means of biopsies that the hepatic lesion of the usual form of the malady can be observed. Moreover, the biopsy method permits one to compare one stage of the disease with another and to observe the progress and regression of the changes. It will be convenient to describe first the lesions of the acute preicteric and icteric stages and then those observed in the posticteric stage.

I. *Acute Stage.*—Fifty-four biopsies were obtained from patients believed to be in the acute or progressive phase of the disease. These cases fell readily into four groups, whose distribution is shown in table 1.

Twenty characteristic cases were selected to illustrate various stages of the icteric phase. These provided control material for comparison with nonicteric stages of the disease and with atypical cases in which clinical jaundice never developed. Thirty-four patients were chosen who manifested the usual prodromes of the preicteric stage. Nine of these subsequently became jaundiced and are classified as preicteric. Seven never developed clinical jaundice but within the expected period a transient rise of serum bilirubin to levels below 2.5 mg. per cent was observed. We have called these subicteric cases. Eighteen other cases never showed either clinical or chemical evidence of bilirubin retention and are classified as nonicteric. A description of the microscopic observations in the various groups follows:

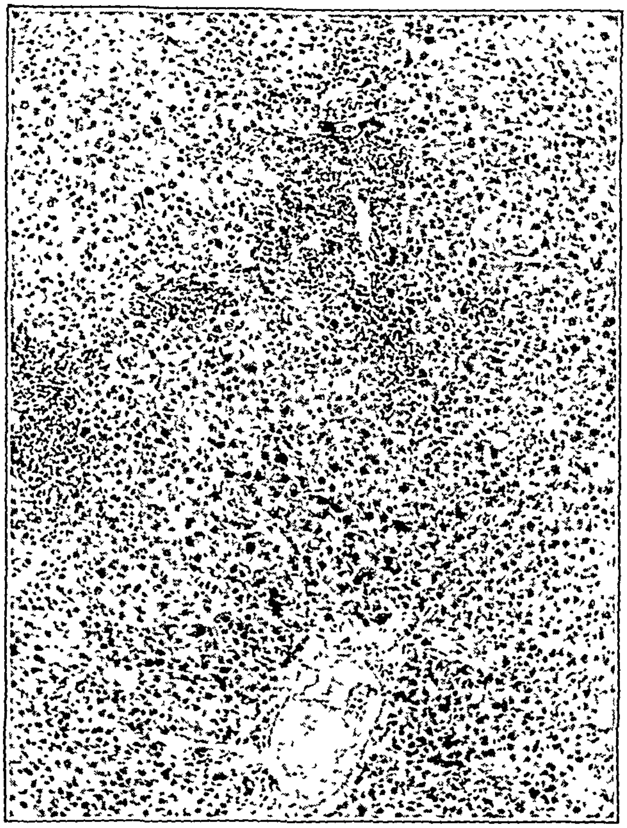

Fig. 1.—Preicteric case: Biopsy on the seventh day of illness, jaundice appeared on the eighth day. It shows perilobular infiltration, extension into the lobule, prominence of reticuloendothelial cells and lobular disarray.

A. The Icteric Stage: Six features were found to be constantly present in the icteric stage, though the severity of any one change and of the total syndrome varied over wide limits.

1. Periportal inflammatory infiltration: This does not differ significantly from that observed in the fatal cases. It is always predominantly mononuclear. Histiocytes and lymphocytes are most numerous, but plasma cells are usually present. Neutrophils and eosinophils can always be found, and the latter are occasionally numerous. The cells show no evidence of degeneration or necrosis. In many instances a tendency for the inflammatory cells to infiltrate the periphery of the lobule is apparent.

2. Intralobular inflammation. Within the lobule itself the reticuloendothelial cells are everywhere conspicuous due to swelling and hyperchromatism. They frequently contain both biliary pigment and droplets of fat. There are also many focal collections of histiocytes, some of of which may be formed locally, perhaps from Kupffer cells, since mitoses are occasionally seen. They may lie either within the sinusoidal lumens or in the space of Desse. Frequently they are clumped about the remnant of a necrotic liver cell which has been extruded from the column.

3. Lobular disarray: The normal radial arrangement of the hepatic cords is commonly obscured. They vary in width as the result of shrinkage of some cells and swelling of others. They seem to twist and kink, and their continuity is frequently interrupted. The reticular pattern is distorted, and foci of condensation may be apparent.

4. Liver cell degeneration and necrosis: In the biopsy material studied by Horan, Jolliffe and myself[18c] acute central necrosis of the autolytic type characteristic of the fatal form of the disease was not observed. In contrast all cases showed another form of necrosis mentioned by Roholm and Iversen[15] and Dible and associates,[16] but first fully described by Axenfeld and Brass.[17a] This consists of acidophilic degeneration of individual cells at any point in the lobule. The stippled cytoplasm of the normal cell becomes homogeneous and intensely eosinophilic. The nucleus becomes first pyknotic, then fragmented and finally disappears. The cell separates from its neighbors and from the sinusoidal membrane, loses its polygonal shape and shrinks into a hyaline spherical body somewhat resembling the Councilman body of yellow fever. This is extruded from the cell column and passes into the space of Desse or sometimes into the sinusoidal lumen. In either location it may form the focus for a collection of monocytes.

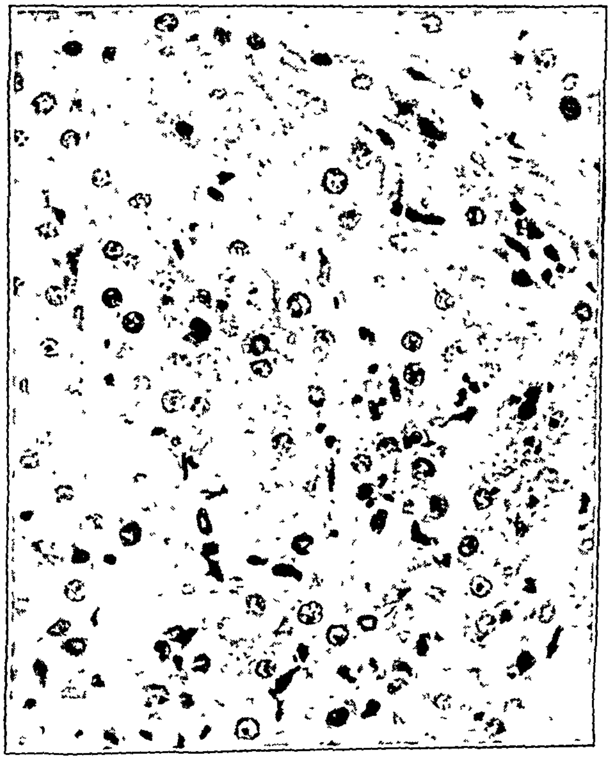

Fig 2.—Subicteric case. Biopsy on ninth day of illness. The patient was never clinically jaundiced. The serum bilirubin level rose to a maximum of 1.52 mg per hundred cubic centimeters. The hepatic cords appear disorganized Various stages of acidophilic necrosis of liver cells are apparent. There is an increase in the number and prominence of endothelial nuclei

Another but much less frequent evidence of hepatic cell degeneration is a ballooning of the cytoplasm. The cell may increase to four or five times the normal diameter; the cytoplasm becomes extremely pale and appears to consist of widely separated granules, but fat is not demonstrable. The nucleus may become atypical, and the cells are frequently multinucleate. This type of change is usually restricted to the central portion of the lobule.

5. Regeneration: Throughout the active phase of the disease mitotic figures are readily found in liver cells. They are particularly numerous in the acute stages and often seem disproportionate to the amount of visible necrosis. Five or more mitoses are frequently present in a single field, and multipolar mitoses are by no means infrequent. It is possible that the numerous multinucleate cells represent abortive, unsuccessful attempts at cellular multiplication.

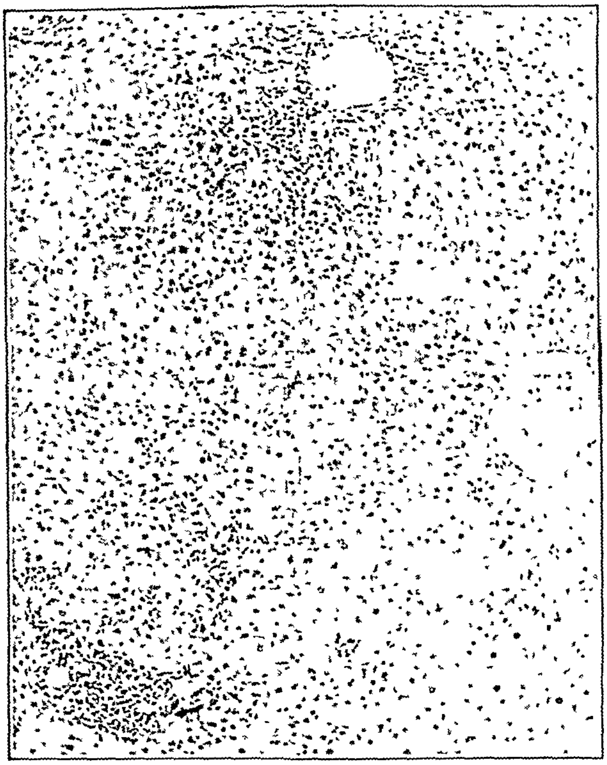

Fig 3—Acute nonicteric case· Biopsy on fifth day of illness The maximum serum bilirubin was 0.25 mg. per hundred cubic centimeters The icteric index was 4 The cephalin flocculation readings were 3/4 and 4/4 plus. Low power magnification shows mild periportal inflammatory infiltration but many foci of inflammatory cells within the lobule.

Mitoses in biliary duct epithelium are much less frequent. Elongation and convolution of the ducts, however, indicate proliferative activity in the majority of cases.

6. Biliary Stasis: In icteric cases the biliary canaliculi are slightly dilated, and biliary thrombi can regularly be found if they are not dissolved in the process of paraffin imbedding. Small droplets of bile are also present in the cytoplasm of the liver cells. Both of these processes are most apparent and usually restricted to the central portion of the lobule.

B. Preicteric Cases: In 7 of the 9 patients in this group overt jaundice developed within one to seven days of the time of biopsy. The biopsies were taken from the fifth to the fourteenth day of illness. In all 7 specimens periportal and intralobular inflammation, lobular disarray, focal necrosis and mitotic activity were apparent in a severity equal to or surpassing many of the icteric cases (fig. 1). Biliary stasis was present in only 1 case in which a biopsy specimen had been taken twenty-four hours before the appearance of jaundice.

In the 2 remaining cases jaundice developed thirty and thirty-one days following biopsy. Since this is well beyond the usual duration of the preicteric period, it is impossible to be certain whether or not the patients were infected at the time of biopsy. The biopsy from 1 was entirely negative and from the other showed only questionable changes.

C. Subicteric Cases: In 5 of the 7 subicteric cases the observations were qualitatively indistinguishable from those of the preceding (preicteric) group. No case showed biliary stasis, and the intensity of inflammatory, degenerative and regenerative phenomena was not much below that observed in the preceding group (fig. 2). In 1 case biopsied on the fourth day of disease the changes were minimal and in 1 taken on the seventh day no abnormality was observed.

D. Nonicteric Cases: Eighteen suspected cases never showed either clinical or chemical evidence of bilirubin retention despite close study. In 5 of these all the usual changes except biliary stasis were present in mild to moderate degree (figs. 3 and 4). In 5 others, one or more criteria were positive but the remainder were absent, and the observations were considered equivocal. In 8 cases the biopsy specimen was completely normal.

II. *Posticteric Stage.*—Abundant clinical evidence such as the persistence of symptoms, physical signs or abnormal results of laboratory tests suggests that the disease may not terminate coincidentally with the disappearance of clinical jaundice. Many cases in the recovery phase were therefore selected for study, including examples of apparently normal convalescence and of delayed recovery. The distribution of these cases by

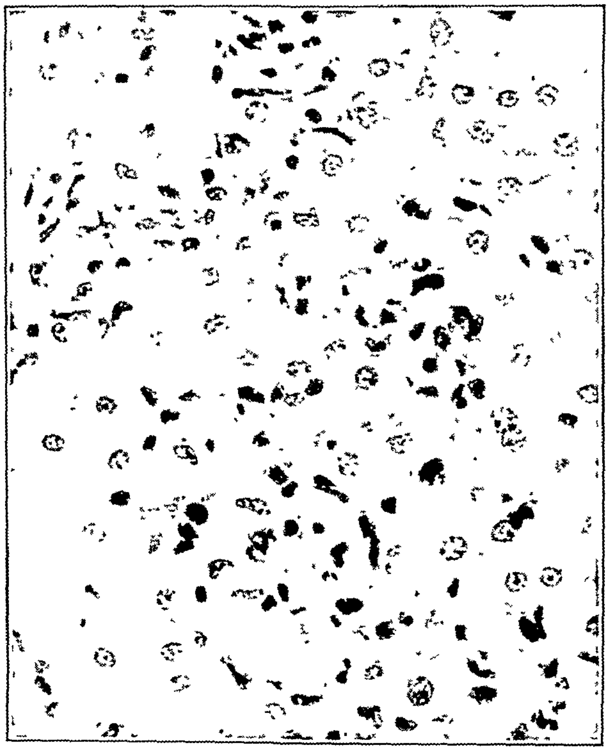

Fig 4.—Same case as figure 3 Detail from midzone of lobule to show pronounced disorganization of hepatic columns, prominent Kupffer cells and foci of histiocytes. Many of the last mentioned are collected about necrotic liver cells which have been extruded from the hepatic columns

clinical groups and the incidence of positive histologic observations is shown in table 2.

A. Normal Recovery Group: Of the 20 convalescent patients constituting this group 2 had not had biopsy specimens taken in the acute stage of the disease. The remaining 18 had had previous biopsies, and all but 2, a subicteric and a nonicteric case, respectively, had proved histologically positive. The dates of rebiopsy ranged from the thirty-fourth to the one hundred and thirty-first day from onset, twenty-five to one hundred and ten days after the appearance of jaundice. Seven of the repeat biopsies, including the 2 previously negative, showed no significant abnormalities. Five cases showed minimal changes which were regarded as of doubtful significance. In the remaining 8, definite evidences of persistent hepatitis were present. Most constant of these changes was continued periportal inflammatory infiltration (fig. 5). Frequent also were intralobular inflammatory foci and hyaline necrosis of occasional hepatic cells. The lobular disarray had usually though not invariably cleared, and mitoses had entirely disappeared. Only 1 case showed slight persistent biliary stasis. Multinucleate cells had frequently increased in number. A new phenomenon, seldom seen in the acute stage, was the development of fat vacuoles in many of the liver cells.

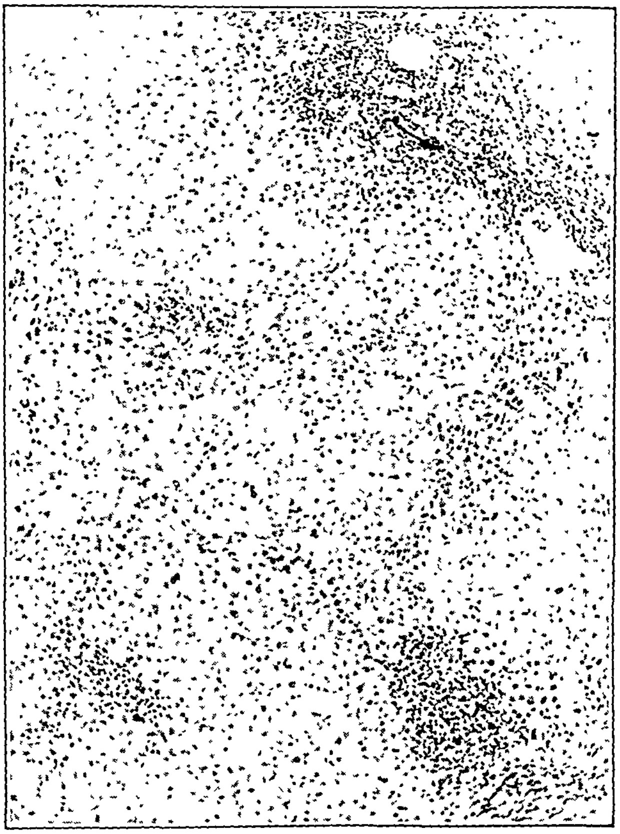

Fig. 5.—Normal convalescence. A biopsy taken on the eighth day of illness, the fifth of jaundice, had shown moderately severe hepatitis. This biopsy was taken forty-nine days later. It shows persistent periportal infiltration. The intralobular lesions have almost but not quite resolved.

The rate of recovery from hepatitis even in the clinical group of normal convalescents evidently varies over wide limits. In 2 cases examined on the thirty-second and thirty-third days the hepatitis had almost cleared, and 4 cases observed between the forty-fifth and fifty-third days revealed entirely normal conditions. Only 2 of the latter had shown severe lesions on the first biopsy. At the other end of the scale, 1 case studied on the eighty-third day from onset, the seventy-third from the appearance of jaundice, still showed moderately severe activity.

B. Recrudescences: One of the most obvious reasons for delayed recovery was a recrudescence of the acute symptoms of the disease during convalescence. Such episodes commonly occurred from the thirtieth to fiftieth day of the disease and were often of clinical severity equal to or even greater than the original attack. Three of the examples studied were at the peak of the recrudescence, the others at intervals from twenty-four to one hundred and thirty days after the second appearance of jaundice. The changes differed in no way from those observed in biopsies taken at equivalent time intervals during or succeeding an initial attack.

C. Recurrent Attacks: Recurrence of hepatitis after a prolonged interval of normal health is by no means rare. Biopsy specimens were obtained from 3 patients with such attacks. The recurrence developed 300, 360 and 390 days after the original attack, and the biopsies were made 3, 48 and 97 days after the onset of the second episode. The first was indistinguishable from the acute stage of an initial attack, the second was entirely normal and the third showed only equivocal evidence of abnormality. No trace of permanent hepatic damage attributable to the first attack was found in any case.

Table 2.—*Posticteric Stage of Hepatitis*

Group	Number	Hepatitis Positive	Hepatitis Doubtful	Hepatitis Negative
Normal recovery	20	8	5	7
Recrudescence	16	10	6	0
Recurrent attacks	3	1	1	1
Delayed recovery	40	15	10	15
Chronic nonicteric	10	1	2	7

D. Delayed Recovery: Forty cases were classified clinically as instances of delayed recovery because of the persistence of symptoms, signs or abnormal laboratory observations or some combination of these factors. Biopsies were obtained over a wide range of time from one hundred to five hundred days after the onset of the acute attack. In 15 the livers were normal, in 10 the observations were minimal and were recorded as doubtful and in 15 they were clearly positive. In the last 15 the changes were essentially similar to those in the normal convalescent group; periportal and intralobular inflammation and focal hyaline necrosis persisted, but biliary stasis and lobular disarray had cleared and mitoses were seldom found.

E. Chronic Nonicteric Group: One final group of 10 clinically debatable cases remains. They had been clinically diagnosed as chronic hepatitis without jaundice. These patients gave no history of an acute icteric episode. In 3 an abrupt onset with symptoms characteristic of the prodromal period suggested an attack of subicteric or nonicteric hepatitis. In 3 others the history of acute onset was questionable, and in the remaining 6 none could be obtained. These patients were clinically indistinguishable from the delayed recovery group. For periods ranging from eighty to three hundred days they had complained of symptoms such as easy fatigue, anorexia and fat intolerance. The livers were palpable and frequently tender, and a scattering of laboratory tests was positive. In only 1 case from the group with abrupt onset were the results of the functional tests consistently abnormal: a cephalin cholesterol flocculation test of 4 plus in both tubes at the end of twenty-four hours, sulfobromophthalein sodium retention of 40 per cent and a bilirubin level of 1.7 mg. per hundred cubic centimeters. This case alone in the group showed positive histologic evidence of active hepatitis. Two other cases which showed occasional foci of acidophilic necrosis but no inflammatory changes were classed as doubtful. Two of the remaining 7 specimens were entirely normal. The other 5 showed nonspecific changes, such as fat vacuolization or slightly enlarged hydropic cells, which could not be regarded as evidence of hepatitis.

COMMENT

Comparison of Epidemiologic and Clinicoanatomic Classifications of Hepatitis.—In the introduction four epidemiologic types of hepatitis were mentioned, the sporadic and the epidemic forms of the naturally acquired disease, homologous serum jaundice and hepatitis due to arsphenamine. Are there corresponding anatomic variations? The verdict of all groups working with the biopsy technic is unanimously negative. Roholm and Iversen's material included both sporadic and arsphenamine-treated cases, and they could distinguish no differences. Axenfeld and Brass compared sporadic and epidemic cases and found them identical. Dible, McMichael and Sherlock compared epidemic hepatitis, arsenotherapy jaundice and homologous serum jaundice and likewise concluded that the pictures were indistinguishable. My own biopsy studies of epidemic cases are in close agreement with all these three series.

Lucké and Mallory showed that most cases of fatal hepatitis fell into two types, the subacute and the fulminant form. A large proportion of the cases in the latter group occurred in severely traumatized or wounded men who had received plasma or whole blood as a resuscitative measure. The interval between injury (and, by implication, transfusion) and the development of jaundice ranged from thirty to one hundred and twenty days with 60 per cent of the cases falling in the fifty to ninety day interval. This range is well within the known incubation period of homologous serum jaundice, and it seems fair to assume that most of the cases may be so classified. The relative distribution of the two types of disease in wounded and nonwounded patients is shown in table 3.

It is evident that the spontaneous disease can run either a subacute or a fulminant course and that in this series of severely wounded men the homologous serum type was overwhelmingly of the fulminant variety. These observations are balanced, however, by Lucké's 1942 series of cases, which were all of the subacute variety, despite the fact that the majority were homologous serum jaundice secondary to vaccination against yellow fever. The method of infection is evidently not the explanation of variations in clinicoanatomic type, and if different viruses are involved [1c] they produce identical effects.

Types of Degeneration and Necrosis of Liver Cells.—In fatal cases of hepatitis massive central necrosis of the autolytic type has been invariably found. In biopsy material from nonfatal disease it may be present [20] but is exceptional. The only patient of Roholm and Iversen to show it died shortly after biopsy. It was present in none of my cases at the time of biopsy, but its former presence could be inferred in 1 instance from condensation of the reticulum about the central vein.

Another feature frequently recorded in biopsy studies of hepatitis has been variously described as hydropic [20a] or granular [13] degeneration of liver cells. This also is inconstant and is usually seen in the severer cases. It was present in 9 acute cases in this study but was extensive in only 3. It is most definite in the center of the lobule, is frequently associated with central necrosis and may well be its precursor, as Roholm and Iversen suggested.

In contrast to these inconstant phenomena the acidophilic, hyaline necrosis of individual cells was invariably found in all progressive stages of the disease. This also was the experience of Axenfeld and Brass. They described it as most frequent in the center of the lobule, but in my material it appeared to be scattered indiscriminately without lobular orientation. It is necrosis of this type which appears to be primarily responsible for the disorganization of the hepatic columns which is such a conspicuous feature of the acute stage.

Central necrosis, which is so constant a feature of autopsy material, has not in my experience proved characteristic of the typical and therefore nonfatal case of hepatitis. It is so different in character and distribution from the acidophilic, coagulative necrosis of individual cells that an entirely different mechanism probably is involved.

Table 3.—*Duration of Disease in One Hundred and Seventy-Eight Cases of Fatal Hepatitis*

Duration, Days	Wounded (Inoculation Jaundice)	Not Wounded (Epidemic and Sporadic)
Less than 10	58	34
10 to 19	16	23
20 and over	3	44
Total	77	101

Nonicteric Hepatitis.—The material in this study provides abundant evidence that active hepatitis may exist without clinical jaundice. All cases of hepatitis have their nonicteric stages. The liver already shows severe degenerative, regenerative and inflammatory changes in the earliest biopsies, which were obtained from one to seven days before the development of clinical jaundice. Active hepatitis furthermore persists several to many weeks after the disappearance of clinical jaundice, even in cases which appear to be making a normal clinical recovery.

The existence of nonicteric hepatitis has repeatedly been inferred to explain certain epidemiologic features of the disease.[10] A single case with histologic verification was reported by Axenfeld and Brass. My associates and I have found numerous examples in our own material. They fall into two types on the basis of the serum bilirubin levels. In one, elevations of serum bilirubin to levels from 0.7 to 2.0 mg. per hundred cubic centimeters were observed, in the second repeated checks failed to demonstrate any rise above the normal level. The histologic observations in both these groups exhibited all the criteria of hepatitis except biliary stasis. Though the average intensity of inflammatory and degenerative change was slightly below that manifested in the icteric group, there was much overlapping; in several instances nonicteric cases showed severer lesions than did the frankly icteric ones. We were unable to recognize any consistent anatomic basis for the development of icterus.

SUMMARY

The pathology of fatal and nonfatal hepatitis has been compared on the basis of a survey of 296 autopsy reports and 160 biopsies from 137 cases of nonfatal disease.

Epidemic hepatitis, in either fatal or nonfatal form, is characterized pathologically by the simultaneous occurrence of inflammatory and degenerative changes in the hepatic parenchyma. In fatal cases the degeneration takes the form of massive autolytic necrosis, which in some areas may be followed by extensive regeneration. In benign cases massive necrosis is seen only exceptionally, whereas acidophilic coagulative necrosis of individual cells is constantly present. Other changes found in the progressive stage of the disease are disorganization of the lobular pattern, focal intralobular collections of inflammatory cells and active regeneration of the liver cells. All these factors are present in the prodromal period of the disease before jaundice becomes apparent, and many of them may persist for weeks after it has disappeared. Evidence has been presented that acute epidemic hepatitis with histologically characteristic involvement of the liver may run its course without the development of clinical jaundice.

JAUNDICE IN RELATION TO CIRRHOSIS OF THE LIVER

STOCKTON KIMBALL, M.D.
WILLIAM H. C. CHAPPLE, M.D.
and
SAMUEL SANES, M.D.
Buffalo

In the course of a recent analysis of the effect of treatment of patients with decompensated Laennec's cirrhosis,[1] we were impressed with the increasing incidence of jaundice in recent years. We are reporting our observations in order to propose some questions concerning the part that this jaundice plays in the life cycle of cirrhosis, especially of Laennec's cirrhosis.

Rolleston and McNee (1929) say: "Jaundice is not a prominent feature in portal cirrhosis, but it is met with at some time in the course of the disease in more than one third of the cases. Thus in 293 cases, obtained by combining the statistics of Fagge, Yeld and Sears and Lord, jaundice was recorded in 107, or 36.5 per cent. Eppinger estimated that it occurred in half the cases. The jaundice is usually slight and often transient. It may be merely an incident in the course of the disease, and have passed away before the patient comes under observation with indubitable cirrhosis. . . . Functional failure of the liver cells probably plays a more important part than biliary obstruction in the production of the jaundice."[2] Ratnoff and Patek[3] found jaundice in 65 per cent of patients in their series and placed emphasis on its frequency. Since this time a number of writers have confirmed this observation.

Features to be emphasized in the report herewith presented are (*a*) the frequency of the jaundice (four fifths of cases) in the 1941 to 1945 period and (*b*) the increase in the incidence of jaundice, which doubled between the 1936 to 1940 period and the 1941 to 1945 period.

The patients on whom this report is based fall into two groups seen during two periods of five years, 1936 to 1940 and 1941 to 1945. The 1936 to 1940 group we have labeled A, the 1941 to 1945 group, B. The patients in group A were treated symptomatically with a house diet, mersalyl, paracentesis and withdrawal of alcohol. The patients in group B were treated in addition with a high protein (150 to 250 Gm.), high carbohydrate (350 Gm.), low fat (60 Gm.) and high vitamin diet, according to the concept introduced by Patek in 1937.[4] The incidence of visible jaundice in group B was double that in group A. Despite this fact the death rate in group B was three-fourths that of group A and the survival time of patients in group B was two to four times that of those in group A.[1]

In an effort to minimize error we have excluded from our study all cases except those in which the clinical diagnosis of Laennec's cirrhosis appeared unquestioned. All the cases analyzed showed signs of hepatic decompensation. As evidence of decompensated cirrhosis we accepted the following: ascites, edema of the ankles, obvious splenomegaly, esophageal varices as demonstrated roentgenologically or by gross hematemesis or melena. Jaundice was not included as an evidence of hepatic decompensation. To avoid confusion concerning the nature of edema of the ankles and ascites, and despite the fact that Laennec's cirrhosis and cardiac decompensation may often coexist, we have excluded all cases which show evidence of cardiac decompensation. Since this is a study of clinically evident cirrhosis, we have not included in the present analysis cases in which Laennec's cirrhosis was demonstrated at autopsy but either was not suspected clinically or did not give clinical evidence of hepatic decompensation.

In selecting the cases for analysis we attempted to study all the charts filed in the record room under the diagnosis of cirrhosis of the liver. This was impossible in the earlier group, since the charts were being microfilmed and were not all available for study. From the earlier period, A, 160 successive unselected charts were studied and compared with 200 successive unselected charts from the later five year period, B. In the first five year period, A, our information was obtained entirely from the charts. One of us, Dr. William H. C. Chapple, has seen most of the patients in the second five year period, B, and has done most of the work for this paper. The histologic slides were reviewed by Dr. Samuel Sanes.

Table 1 shows the diagnosis noted in this group of 360 cases. It will be seen that of 160 patients in the first five year period, A, 57 who demonstrated clinically decompensated cirrhosis have been included for analysis and of 200 patients in the second five year period, B, 86 have been included for analysis.

Our patients were seen in the general ward service of a city hospital required by law to admit all who apply, including the persons with chronic and recurrent

alcoholism. The conditions for clinical study and control of treatment were good. The interest of the members of the staff in vitamin deficiencies was strong. Opportunities for outpatient follow-up after discharge of the patients were excellent, but the chronic alcoholic addicts seldom availed themselves of this opportunity. At home they occupied themselves more consistently with drinking than with eating. When they again required hospitalization they generally returned to the same service, since other hospitals in the city do not welcome persons with chronic alcoholism. This presented an excellent opportunity for follow-up studies.

The percentage of patients who were confirmed and chronic alcoholic addicts and the percentage of those who showed clearcut evidence of vitamin deficiency are shown in table 2. It is probable that the difference in occurrence of vitamin deficiency represents a difference in observation and recording rather than a true difference in incidence. The deficiencies noted include: bleeding tendencies such as purpura or bleeding gums; cheilosis; atrophic, red or purple tongue; pellagra; peripheral neuritis, and combinations of the foregoing.

Table 1.—*Comparative Study of Five Year Periods*

	A	B
Alcoholic addicts with large livers	42	67
Other alcoholic addicts, cardiac cirrhosis	42	22
Autopsy only	19	25
Decompensated cirrhosis	57	86
	160	200

Table 2.—*Etiologic Classification*

Group	Total Cases	Chronic Alcoholism	Clearcut Vitamin Deficiences
A	57	36	5
B	86	79	35

The physical observations are listed in table 3. It will be noted that the reported incidence of palpable livers is high. How many of these livers were enlarged is open to question. There was at times actual enlargement; but even when a liver is reduced in size, as proved at autopsy, it is so increased in firmness that on deep inspiration its edge is often felt below the costal margin. The incidence of spider angiomas noted on the tables is certainly below the actual incidence. The same is true of the reported occurrence of signs of vitamin deficiency, especially as seen in the tongue.

It is evident that whatever may be the etiologically significant factors in Laennec's cirrhosis, alcoholism is a dominant factor and nutritional deficiency a significant factor in the life history of the patients in this series. We are raising this question: How far may intrahepatic damage associated with attacks of acute jaundice play a part in the progress and terminal picture of Laennec's cirrhosis?

The incidence of jaundice (table 3) doubled in the second as compared with the first five year period. This was jaundice which was clinically, not merely serologically, evident. The history of jaundice is summarized in table 4. In all but 3 cases, 1 in group A and 2 in group B, the jaundice was present at the time of admission or developed while the patient was in the hospital for treatment of his cirrhosis. These 3 patients had had jaundice in the past but did not manifest it while they were in the hospital. Four patients in group A and 21 in group B had had one or more attacks of jaundice preceding the attack present during this hospitalization. In 2 instances in each group these earlier attacks had been more than five years before. In the remaining 2 in group A and 19 in group B the previous attacks had been within a five year period, the majority during the year preceding hospitalization. On the other hand, in one third of the patients in group A and in over one half of the patients in group B the initial attack of jaundice was either a part of the illness which brought the patient to the hospital or developed after he entered the hospital.

Table 3.—*Physical Observations*

	A	B
Total	57	86
Liver palpable	18	75
Spleen palpable .	7	16
Spider angiomas . ..	1	33
Ascites	47	67
Esophageal Varices	13	25
(Deaths in group with varices)	(11)	(9)
Jaundice	23	69
(Terminal only)..	(16)	(23)

Most striking is the increased incidence of jaundice in the second five year period (*B*) as contrasted with the first five year (*A*) group. This contrast in incidence applies both to the patients who had had earlier attacks and to those in whom jaundice developed for the first time as part of the hospitalizing illness. The recovery rate in the presence of jaundice was far greater in the second than in the first five year period. Of 18 patients in group A in whom jaundice appeared for the first time as part of the hospitalizing illness, 16 died—that is, the jaundice was part of the terminal picture. Of 46 patients in group B whose initial jaundice coincided with hospitalization only 23 died and 23 recovered. This suggests an incidence of recovery from active hepatic disease considerably greater in the second period of five years than in the first.

Table 4.—*Jaundice*

	A 1936 to 1940	B 1941 to 1944
Jaundice		
Preceding; without attack during admission	1	2
Jaundice on or during admission		
+ 1 attack more than 5 years ago.... . ..	1	1
+ several attacks more than 5 years ago ..	1	1
+ 1 attack within 5 years..	1	14
+ several attacks within 5 years	1	5
Transitory (no previous attacks)....	2	23
Terminal (no previous attacks)	16	23
Total	23	69

What is the significance of this increasing frequency of jaundice? And why does it now appear to be a less ominous sign in cirrhosis than it was in former years?

The fourth patient likewise gave no history of alcoholism. She also denied dietary deficiency, but in the light of the low serum protein (5 mg. per hundred cubic centimeters) the reliability of her history is questionable. Figures 1 and 2, low and high power views of the liver (case 5), show the fatty changes, the hepatic cell degeneration and the periportal connective tissue found in these patients. The degree of cirrhosis in the fourth case was the least of the 3, although the degree of fatty change and acute cellular damage resembled that in the other 2 cases. In case 5 the patient was an alcoholic addict under observation for twenty years who was originally admitted in 1925 with a diagnosis and clinical picture of acute catarrhal jaundice or acute hepatitis, with recurrence of jaundice the following year. After this he was free of evidence of hepatic disease for fifteen years. During these years he was observed twice as the result of hospitalization for fractures. At the end of this period there developed the characteristic signs of decompensated cirrhosis, and he died. Laennec's cirrhosis and acute hepatic cellular damage were found at autopsy.

SUMMARY

An analysis of 143 cases of decompensated Laennec's cirrhosis, chiefly in persons with chronic alcoholism, is presented. Of these, 57 were seen in the first five year period, 1936 to 1940, and 86 in the second five year period, 1941 to 1945. During the 1941 to 1945 period a high protein, high vitamin, low fat diet was employed. The mortality in the latter period was three-fourths that of the former, and the survival time of patients in the latter group was two to four times that of patients in the former group.

The incidence of clinical jaundice in the earlier group was half that observed in the later group. In all but 3 instances the jaundice was a part of the illness for which the patient was hospitalized. There was a history of one or more attacks of jaundice preceding the attack associated with hospitalization in 4 patients in the first and in 21 patients in the second five year period.

All the patients who came to autopsy or were biopsied (22 and 26 in groups A and B, respectively) showed portal cirrhosis, save 1 who manifested a toxic cirrhosis. The cases of several patients who showed in addition decided fatty and degenerative changes in the liver cells are reported. One of these had been followed for twenty years between the attack of "catarrhal jaundice" and the appearance of the terminal decompensated cirrhosis.

That jaundice may be a manifestation of damage to liver cells is suggested by the fact that approximately one fourth of the jaundiced cirrhotic livers studied histologically showed excess fat and acute damage to hepatic cells.

In consideration of these fatty and regressive changes, of the increased frequency of jaundice and of the improved response to therapy, two questions have been raised:

1. Can acute epidemic hepatitis or recurring attacks of hepatitis play any etiologic role in the development of Laennec's cirrhosis?
2. How much does recurring jaundice on the basis of liver cell damage in an already established cirrhosis influence the clinical course of the disease and the pathologic condition of the liver?

NEEDLE BIOPSY OF THE LIVER

F. W. HOFFBAUER, M.D.
Minneapolis

Needle biopsy of the liver is a means of securing a strip of hepatic tissue for histologic examination by a relatively simple procedure that can be performed at the patient's bedside. The idea is not new. It was first suggested in 1895.[1] Although a few investigators in Europe employed the method, it received little attention until 1939. Since then there have been many reports on its application. Table 1 lists the references to the literature that have been examined.

In addition to the references listed, other series of cases as yet unpublished have been made known to me. Iversen[2] in Copenhagen, Denmark, states that over 600 biopsies have now been performed in his clinic. Davis[2] in New Orleans has recently completed a series of 96 cases; Schiff[2] and his co-workers in Cincinnati have performed 60 such examinations, and Ducci[2] in Santiago, Chile, has done 62.

The method first described by Iversen and Roholm[3] in Copenhagen has been widely employed. The information gained by application of this method has been noteworthy. The reports of Roholm and Iversen[4] and of Dible, McMichael and Sherlock[5] on the pathology of infectious hepatitis are examples. These remarkable studies have furnished a basis for better understanding of this disease. Krarup and Roholm[6] have demon-

strated the transition of hepatitis to cirrhosis by means of serial biopsies.

Biopsy of the liver has afforded my associates and me an opportunity to correlate functional changes with the histologic changes in some instances.[7] Increased interest in the study of hepatic disease has been aroused, and more accurate diagnoses have been made possible by the addition of biopsy methods to laboratory studies.

METHODS OF NEEDLE BIOPSY

Various methods have been suggested for this procedure. All employ local infiltration of procaine hydrochloride as the anesthetic agent. A hypodermic injection of morphine is usually given thirty minutes before the puncture. It is not always necessary. A fairly large bore needle is inserted into the liver, and a small plug of tissue is obtained. The specimen is usually from 1 to 3 cm. in length and approximately 1 to 2 mm. in width. The strip of tissue is immediately fixed in a suitable agent and later imbedded in paraffin and sectioned. The strip of tissue is admittedly small; figure 1 shows the average size obtained. By careful handling, however, one can apply several types of stains. A remarkable amount of information can often be obtained. The strip may contain anywhere from eight to fifteen lobules of the liver cut at various angles. This is sufficient for diagnostic purposes, especially in diffuse disorders such as hepatitis and cirrhosis.

Intercostal approach to the liver

Iversen and Roholm[8] described an aspiration method for needle biopsy of the liver that has been used by many investigators.[8] The patient is placed in the supine position. The site of insertion of the needle is the ninth intercostal space in the posterior axillary line on the right side. After preliminary procaine hydrochloride infiltration a small cut is made in the skin at this site. The patient is instructed to exhale completely and then refrain from inhaling. A special needle containing a sharp stylet is employed. It is advanced through the pleural space and diaphragm and into the substance of the liver for a distance of several centimeters. The stylet is removed and a syringe is attached to the needle; suction is then applied. By advancing the needle with a slight rotary motion for a distance of 2 cm. a plug of tissue is cut and aspirated. The needle is removed and a small dressing is applied. Since the needle is passed between the ribs, it is necessary to work rapidly; the patient should fix his chest in complete expiration during the procedure. The instrument used is a needle 18 cm. in length and 2 mm. in width. The cutting edge of the needle is not the usual hypodermic bevel type but has, rather, a sharp serrated edge designed to cut out a small cylinder of tissue as it is pushed forward with a rotary motion. Sherlock,[8e] who has had an extensive experience with this method, employs a needle 1 mm. in diameter and 15 cm. in length.

Subcostal approach to the liver

Baron[9] in 1939 reported aspiration biopsy of the liver and suggested that the liver be entered through the anterior abdominal wall, passing below the costal margin on the right side. When the liver is enlarged the needle can be inserted at the right midclavicular line. Baron stated that "in the absence of hepatomegaly, aspiration can be done safely to the right of the epigastrium, immediately below the costal margin and in the general direction of the lower portion of the right axilla." Because of the potential danger, Baron cautioned against the insertion of a biopsy needle between the ribs. He pointed out that the movement of the liver during respiration might result in a tear of the parenchyma of this vascular organ. While the hemorrhage that results from a straight needle puncture wound in the liver has in my experience been slight, I would agree that appreciable bleeding might occur from a linear tear.

In 1941 Tripoli and Fader[10] reported needle biopsy of the liver by subcostal approach. Instead of aspiration they employed the "Vim"-Silverman[11] needle. This ingenious device was described by Silverman[12] in 1938 for use in tumor biopsy. Mention of its application for liver biopsy is made in the report of Tenophyr and Silverman.[13]

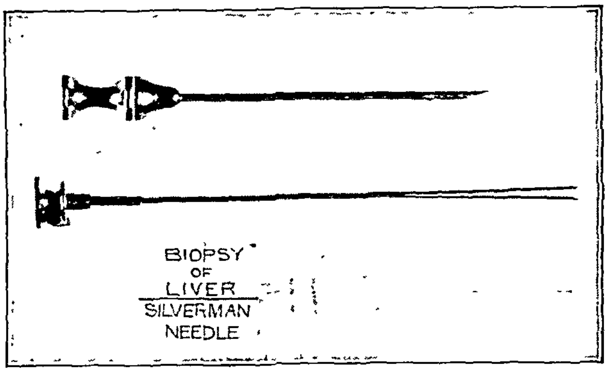

Fig. 1.—The "Vim"-Silverman needle and a microscopic slide showing the usual size of the liver biopsy obtained.

I have employed the Silverman needle (fig. 1) for biopsy of the liver.[14] I limited its employment to patients with hepatomegaly. The usual site of entrance has been the right midclavicular line just below the costal margin. The needle is a 14 gage needle having a hypodermic bevel tip. The biopsy is secured by a smaller needle that is inserted through the 14 gage needle. The inner needle is split longitudinally down the hub. This cuts a small cylinder approximately 2 mm. in width and from 2 to 3 cm. in length. The plug of tissue is trapped between the two prongs and is cut off from its point of attachment by advancing the outer needle over the inner one, the latter being held stationary (fig. 2). Both needles are simultaneously withdrawn. This needle has proved satisfactory for the purpose of biopsy of the liver. Initially, failures occurred in 15 of the 65 cases [14] in which the method was used. These were mainly due to unfamiliarity with the technic and hesitancy to insert the needle a second time if the first attempt failed. Originally the outer needle was introduced with a snug-fitting stylet. When this had penetrated the liver, as noted by movement coincident with respiration, the stylet was removed and the inner needle inserted. This caused some delay and increased the length of time that the needle remained in the liver. At present the stylet is not used. The instrument is first assembled with the inner needle retracted back of the tip. The skin at the point of introduction is incised with a size 11 Bard-Parker blade. Both needles are then introduced, and the biopsy specimen is secured. If one is careful to infiltrate procaine down to the peritoneal surface and to allow a few moments for the anesthesia to take effect, the procedure is relatively painless.

In 1945 Gillman and Gillman [15] reported a large series of aspiration needle biopsies of the liver. They devised a special piece of apparatus for the purpose, one which reduces the manipulations to a minimum. This needle is inserted "in the apex of the angle between the xiphisternum and the right costal margin." According to these authors, the needle is directed slightly upward and to the left until the surface of the liver is reached. Gillman and Gillman have reported a number of valuable observations [16] relative to nutritional changes in the liver. The needle employed by Gillman and Gillman is designed to obviate the removal of the stylet and the attachment of the syringe after the substance of the liver has been entered. The stylet has a spiral groove; it is attached to the plunger of the syringe. The instrument is so constructed that the needle with the stylet in position can be pushed through the tissues; as the needle is directed into the liver, the stylet is withdrawn and suction is applied in a single movement. They found that it was desirable to have the end of the needle beveled like a hypodermic needle rather than with the tip, as used by Iversen and Roholm.

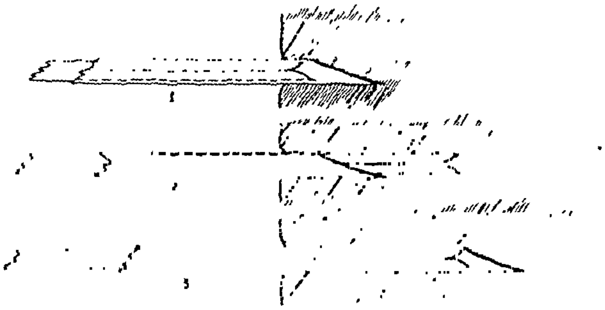

Fig. 2.—Technic of obtaining a biopsy specimen by use of the Silverman needle: (1) the inner needle is retracted until the liver is entered; (2) it is then advanced and a strip of tissue cut; (3) the outer needle is then advanced over the inner, and the tissue fragment is trapped.

The Roth-Turkel needle [17] has been successfully employed by Davis [2] and by Bierwaltes and Mallery.[18] This needle is widely used in this country for biopsy purposes. It has a serrated cutting edge. The prime feature of this instrument is that the cutting needle is contained within another needle which has a long bevel. This facilitates the introduction of the needle into the liver. The biopsy is taken by advancing the longer inner needle through and beyond the tip of the outer one. Davis states that in his experience this needle is more satisfactory than the Silverman needle because the specimen obtained is larger. Suction is usually employed when the Roth-Turkel needle is used.

DANGERS AND COMPLICATIONS

Raby [19] has recently discussed the complications of liver biopsy by the needle method. He described 2 fatalities, both in elderly patients. The danger of needle biopsy was the subject of a recent editorial comment in THE JOURNAL.[20] Roholm, Krarup and Iversen [8a] prepared an extensive review of the subject in their report of 297 biopsies. As complications they listed the following: (1) pain, (2) damage to neighboring organs, (3) implantation of tumor cells in the needle track, (4) air embolus, (5) infection, (6) bile peritonitis and (7) hemorrhage.

Pain following the biopsy is said to occur in about 5 per cent of cases in which the Iversen and Roholm technic is employed. The discomfort does not persist for more than a day. In my experience, pain after the biopsy has not been a prominent feature. In a few instances signs of local peritoneal irritation have been observed. This has been attributed to the presence of a small amount of blood that escaped from the puncture site.

Damage to neighboring organs is a potential danger, especially when the subcostal or anterior approach is employed. I have heard of 1 death in this country from peritonitis after an attempted needle biopsy of the liver. Autopsy disclosed a perforation of the colon. In this case, which was not reported, the mistake lay in the attempt to obtain the biopsy in a situation in which the liver was not easily palpable below the costal margin. Baron [9] contended that needle biopsy could be performed safely by the anterior subcostal approach in the absence of hepatic enlargement. Chiray, Fiessinger and Roux [21] limited their attempts to patients with palpable liver. Davis [2] also selects his cases on this basis.

The complications of implantation of tumor cells in the needle track, air embolus and infection can largely be avoided by careful technic. Needless to say, the entire procedure must be performed with strict aseptic technic. In diseases such as cholangitis, in which one suspects intrahepatic suppuration, needle biopsy is, of course, hazardous and should not be attempted.

Leakage of bile into the peritoneal cavity is a potential danger, especially in the presence of obstruction of the biliary tract. In those instances of cancer of the biliary tract in which my associates and I have performed biopsies no such complication has occurred. The danger of perforation of the gallbladder must be considered.

The chief danger of any biopsy of the liver is hemorrhage. This has been the cause of most of the reported fatalities. The procedure should not be attempted unless one has at hand facilities for blood transfusion. The patient should be kept at rest in bed for twenty-four hours, and the pulse rate and blood pressure levels should be followed at intervals as advocated by Sherlock.[8e] Needle biopsy of the liver should, therefore, be limited to hospitalized patients. The bleeding and clotting and prothrombin time are routinely checked before the method is employed. The amount of blood that escapes from the puncture wound of the liver is not great. In instances in which the puncture was made during peritoneoscopy there was opportunity to observe the bleeding. It seldom lasted for more than thirty to sixty seconds and consisted of a slow trickle of blood down the surface of the liver. In a few instances of chronic passive congestion of the liver bleeding from the site of the puncture was more profuse but not alarming. It might be argued that the tense pneumoperitoneum used during peritoneoscopy has an inhibiting influence on the bleeding.

One serious episode of intraperitoneal bleeding occurred among the cases in which direct needle biopsy was performed at the bedside of the patient. This has been previously reported.[14] The bleeding was found at operation to be coming from a damaged artery beneath the left lobe of the liver and not from the liver itself. The operator passed the needle completely through the thin edge of the left lobe.

There have been a total of 12 deaths ascribed to needle biopsy of the liver in the literature reviewed (table 2). Sherlock [8e] stated the fatality rate as 0.67 per cent. Iversen [2] places the figure as somewhat below 0.5 per cent. It is obvious, then, that needle biopsy entails some risk. It should not be performed indiscriminately. It can furnish so much valuable information, however, that its continued use is believed to be justified in selected cases.

COMMENT

On the medical service of the University of Minnesota Hospitals, needle biopsy of the liver has been attempted in 80 cases since October 1942. These biopsies have been performed at the bedside, using the 3¾ inch (9.5 cm.) "Vim"-Silverman needs as previously described. The procedure has now been restricted to cases in which the liver is definitely enlarged and readily palpable below the costal margin. The method has been of great value in the clinical study of hepatic disease. It has often been of diagnostic aid, especially in parenchymal disorders, such as cirrhosis, hemochromatosis and amyloid disease.

The value of the procedure in the differential diagnosis of the jaundiced patient is an important consideration. The amount of tissue secured is small. The pathologist can usually differentiate obstructive jaundice from hepatitis, a situation in which the clinician often requires assistance. It must be admitted that there are times when such a differentiation will be difficult. This is particularly true if the jaundice is of long standing. Iversen [2] believes that the differentiation can be made with complete accuracy if the biopsy is secured in the first two weeks of jaundice.

In the presence of metastatic carcinoma in the liver the biopsy, performed at the bedside, is of value only if the needle happens to strike a metastatic nodule. This is a situation in which use of the peritoneoscope as an aid in securing the biopsy specimen offers a distinct advantage, since visualization of the surface of the liver is permitted.

NEEDLE BIOPSY OF THE LIVER DURING PERITONEOSCOPY

Some of my earlier experiences with needle biopsy of the liver combined with peritoneoscopy have been described.[7] Kalk, Brühl and Sieke [22] have employed a similar method using the Iversen-Roholm needle. Needle biopsy has now been performed in 50 cases of suspected hepatic disease that have been subjected to peritoneoscopic examination. Initially these were instances in which the liver was not enlarged and direct needle biopsy was therefore deemed unwise. Recently in nearly all instances in which a specimen of the liver for biopsy was desired, the patients have been examined with the peritoneoscope. This was done for purposes of evaluating the two methods.

One of the virtues of the direct needle biopsy has been its simplicity and the relative lack of discomfort which it produces. Peritoneoscopic examination is a much more formidable procedure. It must be done in an operating room. It requires the creation of a tense pneumoperitoneum. Patients usually have much more discomfort following this than they do after the simpler procedure. However, the advantages are great. One can visualize the surface of the liver. Often that alone is sufficient for diagnostic purposes, as for example when there are carcinomatous implants of the surface or when the liver is visibly cirrhotic.

One may well ask, why perform needle biopsy of the liver at the time of peritoneoscopic study when the Ruddock [23] instrument contains a biopsy forceps that may be employed without an additional puncture wound in the abdominal wall? There are two reasons. In my experience it has been difficult to secure biopsies with the forceps. Only when the lower edge of the liver was thin and sharp so that the biting jaws could cut the tissue at the inferior edge have I been able to get a satisfactory specimen. In most instances, particularly those in which the capsule appeared thickened, I have found it impossible to cut through the tissue. A more serious objection to the biopsy taken with a forceps has been the fact that the tissue is obtained from just beneath the capsule. The histologic structure close to the capsule is not always representative of the entire organ. The needle, on the other hand, secures a strip of tissue from a deeper level 3 to 5 cm. below the capsule and affords the pathologist a better opportunity for interpretation.

When the peritoneal cavity is distended with air for the peritoneoscopic examination, the liver falls away from the anterior abdominal wall (fig. 3). The "Vim"-Silverman needle is not long enough to reach the surface of the liver if it is inserted through the anterior abdominal wall just below the costal margin in the right midclavicular line. A longer needle has therefore been used and equipped with a spring guard, as shown in figure 4. The principle, that is, the longer inner split needle, is the same as that devised originally by Silverman. The spring guard has been added to check the progress of the outer needle over the inner, once the tissue plug has been cut. Without the guard, there is a tendency for the outer needle to advance too far beyond the inner one. There is a slight resistance to the passage of the outer needle over the two prongs of the instrument when the tissue plug is trapped within. The operator is apt to push too hard, and the needle then advances farther than is necessary. Deep penetration into the liver is dangerous. On the other hand, if the operator is too cautious and fails to advance the outer needle far enough, the plug of tissue may not be cut off. This has been responsible for some of the failures of this technic. The little spring guard, therefore, allows one to advance the outer needle just the required distance once the cylinder of tissue has been cut.

SUMMARY AND CONCLUSIONS

The literature pertaining to needle biopsy of the liver has been briefly reviewed. The methods employed by various investigators are discussed. The addition of the biopsy to the clinical study of hepatic disease has aroused new interest in the subject. Much valuable information on the histologic changes in the liver in such nonfatal conditions as hepatitis has been made available. The transition of infectious hepatitis to cirrhosis has been elucidated by this means.

The method is not without risk; the chief danger is hemorrhage. Needle biopsy of the liver should not be attempted unless one has adequate facilities for coping with the possible complications that may arise.

On the basis of personal experience, the anterior subcostal approach is considered to be a satisfactory one if the liver is definitely enlarged and easily palpable. In the absence of hepatomegaly, peritoneoscopic examination has been made and biopsy secured by means of a needle inserted through the anterior abdominal wall and guided into place while the liver is visualized. Under these circumstances the needle biopsy is believed to have some virtue over the customary forceps method.

"ALCOHOLIC CIRRHOSIS"

RUSSELL S. BOLES, M.D.
ROBERT S. CREW, M.D.
and
WILLIAM DUNBAR, M.D. *
Philadelphia

The term "alcoholic cirrhosis" is at once misleading. It implies that alcohol produces a certain characteristic type of cirrhosis. This, of course, is not true. There is no gross pathologic or histologic type of cirrhosis that can be identified as alcoholic in origin. Alcoholic cirrhosis is generally accepted as being synonymous with portal cirrhosis, although the latter condition is frequently found in children and adults who have not even remotely had anything to do with alcohol, and despite the fact that in the great majority of alcoholic addicts, as far as is known, cirrhosis does not develop.

It is just a hundred years since Rokitansky stated that "granular liver is one of the most important, though in many respects and especially in reference to its pathogeny, one of the most enigmatical affections of the liver." While some progress has been made in recent years in the study of the pathogenesis of cirrhosis, its cause and mode of development continue to remain part of the mysteries of medicine.

Lest one become too enthusiastic about any of the currently suggested causes of cirrhosis, the status of the numerous theories that have been suggested from time to time in the past should be considered.

One of the earliest and most persistent theories is that concerning alcohol, which will be alluded to presently. Another deals with the intestinal bacteria, which were thought by Adami many years ago to be an important factor in causing cirrhosis because they could be cultured from cirrhotic livers and from the resulting ascitic fluid. Adami did not believe that bacteria were a constant factor in all cases, and he stipulated that before their invasion there must be intestinal irritation from alcohol, acid fermentation or some other agent. Some twenty years ago Longcope showed that lesions resembling those found in cirrhosis could be produced by anaphylactic shock, the result of repeated injection of egg white or other protein. This indicated that protein sensitization and intoxication might originate the disease. Opie and others showed that cirrhosis could be produced by bacterial infections combined with poisons such as chloroform that are toxic to the liver. At the moment it is being assumed that alcohol, in league with diets deficient in protein and certain vitamins, especially of the B group, and diets of low carbohydrate and high fat content are responsible for cirrhosis. Unfortunately, reference cannot be made at this time to all the excellent experimental and clinical studies on this phase of the subject. Of especial interest, however, is the work of Moon,[1] György and

Goldblatt,[2] Connor and Chaikoff,[3] Patek and Post,[4] Jolliffe and Jellinek,[5] Fleming and Snell[6] and others.

In a number of cases attacks of acute and subacute hepatitis, be their causes of a virus, toxic or infectious nature, are thought to be forerunners of portal cirrhosis.

Finally, it is the belief of some students of the subject that disturbances of metabolism are at fault and that cirrhosis is the result of direct toxic affects combined with an allergic reaction (Jaffe[7]).

Ten years ago, on May 13, 1936, to be exact, Boles and Clark[8] presented before this section the results of an analysis of 4,000 autopsies studied at the Philadelphia General Hospital in an attempt to throw some light on the relationship of alcohol to cirrhosis of the liver. At that time we said regarding the role of alcohol, study of which was the primary purpose of the investigation: "It is quite evident from our observations that, contrary to prevailing opinion, alcohol cannot seriously be regarded as a specific cause of cirrhosis of the liver . . ." Furthermore, "As the lesion defined as portal cirrhosis occurs under influences unassociated with alcohol, we would suggest abandonment of the term alcoholic cirrhosis." In 1939 Connor[9] suggested that alcohol did not cause cirrhosis but that the combination of alcohol and a deficient diet which produced fatty changes in the liver eventually led to the disease. In 1940 Boles and Crew[10] reported the results of an investigation of 4,000 autopsies performed at the Philadelphia General Hospital and reached conclusions which were practically identical to those arrived at in the former study made at the same hospital in 1936.

Table 1.—*One Hundred and Forty-Two Cases of Portal Cirrhosis*

Year	Autopsies	Portal Cirrhosis	%
1942-1943	2,000	73	3.6
1945-1946	1,637	69	4.2
Total	3,637	142	3.9

Table 2.—*One Hundred and Forty-Two Cases of Portal Cirrhosis, Age and Sex Incidence*

Age	Male	Female	Total
20 to 29	1	1	2
30 to 39	6	5	11
40 to 49	15	15	30
50 to 59	20	11	31
60 to 69	21	12	33
70 to 79	12	15	27
80 to 89	4	3	7
90 to 99	0	1	1
Total	79	63	142
Ratio	1.25	to 1	

The present analysis is based on the survey of 3,637 autopsies. Two thousand of them were performed in the period from Nov. 15, 1942 to Nov. 15, 1943, and 1,637 were performed during the period from Jan. 1, 1945 to Jan. 1, 1946. Only cases of portal cirrhosis were considered.

Table 3.—*One Hundred and Forty-Two Cases of Portal Cirrhosis, Race and Sex Ratio*

	Male	Female	Total
White	62	51	113
Negro	17	12	29
			142

Ratio: White to Negro, 3.89 to 1

In the 3,637 autopsies studied, 142 cases of portal cirrhosis based on histologic diagnosis were found—or 3.9 per cent (table 1). This is almost identically the same percentage as was found by Boles and Clark in a series of 4,000 autopsies, which was 3.75 per cent.

A study of the age distribution (table 2) shows that the greater number of cases of cirrhosis occur between 40 and 80 years of age, the peak being reached in those between 60 and 69 years of age. It is of interest that almost the same number of cases were observed in the fourth and fifth decades, in as much as ten years ago there were considerable fewer cases noted in these decades. This indicates that while the total number of cases of cirrhosis proved at autopsy has not appreciably increased in the past ten years, a significantly greater number of younger persons are showing evidence of the disease.

The ratio of males to females for all ages in the present group was 79 to 63, or 1.25 to 1. The ratio of males to females between 60 and 69 years of age was 1.7 to 1, whereas in those between 40 and 49 years of age it was 1 to 1. Previous sampling of the total number of persons autopsied at the hospital showed a ratio of males to females of 5 to 4 or 1.25 to 1.

Table 4.—*Accurate History of Alcoholism in Sixty-Four of One Hundred and Forty-Two Cases of Portal Cirrhosis*

Positive	50
Negative	14
	64
Unreliable	78
	142

Cirrhosis is still much commoner in the white race than in the Negro race, the ratio being 113 to 39, or 3.89 to 1 (table 3). The ratio of males to females is approximately the same for the two races. Previous samplings of the total number of persons autopsied at the hospital shows a ratio of total whites to Negroes of 1.6 to 1.

In 64 of 142 cases of cirrhosis, an accurate history concerning the use of alcohol was obtained (table 4).

In 50 cases it was definitely positive. Total abstinence was claimed by 14 persons. In the remaining 78 cases there was either no record of indulgence in alcohol, or the history concerning its use was questionable. It is significant that in younger persons with cirrhosis, namely those under 40 years of age, 9 of 13 admitted heavy drinking. In 3 the history was questionable, and in 1 abstinence was recorded.

A clinical diagnosis of cirrhosis of the liver was made in 50 of the 142 cases proved at autopsy (table 5). That a greater number of cases had not been diagnosed clinically was obviously due to the fact that the disease was in its earlier stages, when there was nothing definite to betray its presence. In 46 of the 50 cases clinically diagnosed, cirrhosis was recorded as the primary cause of death. In 33 of the 50 a positive history of alcoholism was obtained; in 3 others it was negative, and in 14 it was unreliable. Such figures tend to prove that alcohol cannot be absolved from contributing its part to the causation of cirrhosis in an indeterminate number of persons.

TABLE 5.—*Proved Clinical Diagnosis and Accurate History in Fifty Cases of Portal Cirrhosis*

Positive history of alcoholism...........................	33
Negative history of alcoholism...........................	3
Unreliable history of alcoholism.........................	14

TABLE 6.—*Jaundice and Ascites in One Hundred and Forty-Two Cases of Portal Cirrhosis*

			1946	1936
Jaundice.................	40	or	28.0%	30%
Ascites..................	54	or	38.0%	35%
Combined.................	24	or	16.9%	17%

As alcoholism is of such moment at the present time, it is unfortunate that a more careful history concerning its use in all patients, regardless of their disease, is not secured. If cirrhosis is suspected, inquiry is usually made concerning the use of alcohol. If alcoholism is suspected, one may be certain that a diligent search for cirrhosis will be made. Aside from this, relatively little if any attention is given to the matter.

Jaundice was observed in 40 of the 142 cases, or 28 per cent. Ascites occurred in 54 cases, or 38 per cent. Both jaundice and ascites occurred in 24 cases, or 16.9 per cent (table 6). The incidence of jaundice, ascites and the two together was strikingly close to that observed ten years ago. Jaundice at that time was noted in 30 per cent of cases; ascites in 35 per cent of cases and the two combined in 17 per cent of cases. Ruptured varices were noted in 15 cases, or 10.5 per cent.

In recent years the treatment of cirrhosis has been based on the deduction that nutritional deficiencies play a large part in its production. Considerable relief of symptoms, prolongation of life and even apparent cures, though the disease had reached the stage of decompensation and irreversibility, have been claimed by various proponents of such treatment. The results attained are not disputed, but the presumption that the disease is primarily a nutritional disorder can hardly be borne out by the facts. It is assumed that the diet of the chronic alcoholic is deficient in protein, carbohydrate and vitamins, that the storage of glycogen is diminished and that there occurs a fatty replacement of the liver cells. All this may be true, but, except that the liver of the person with alcoholism exhibits various degrees of fatty dystrophy, proof that such is the case is not available. The various studies that have been made concerning the diet of the alcoholic addict are far from convincing, principally because of the small number of persons examined and the relatively short period over which the dietetic survey was conducted.

When one tries to appraise this whole subject of cirrhosis in an unbiased manner, he gives ear to the statements of Karsner,[11] who expressed his opinion in an excellent monograph on the morphology and pathogenesis of the condition that a review of the morbid anatomy of cirrhosis is profitable because it serves to furnish anatomic criteria of recognition and diagnosis. Without such criteria experimental observations may be misleading and may even result in fallacious deductions. The significance of morphologic studies of disease in man may sometimes be overlooked in the fascination afforded by physiologic, chemical and other approaches to the problems of pathology. The principle of the positive identification of the disease in the experimental animal should apply to the investigation of any disease, be it hepatic cirrhosis or any other disorder.

With this in mind one may inquire, after all, how different is this chronic fibrosing disease of the liver, call it chronic hepatitis, atrophic cirrhosis or what you will, from chronic nephritis and other diseases whose pathogenesis is similar, whose eventual pathologic patterns are comparable and whose symptoms are subject to the same variations and environmental influences, and which follow through to the same inexorable termination?

Consider the parallel to nephritis, for example. An attack of acute nephritis may entirely subside or it may smolder, to be reactivated by an infection or some other aggravating influence. On the other hand, it may progress to chronic nephritis. In the case of nephritis, the same difficulty is encountered in nomenclature and classification of types, chiefly because the etiology is unknown. Furthermore, consider the striking similarity in the pathologic process of the two diseases—the early stages of nephritis with inflammatory changes; the later stages with parenchymal degeneration associated with proliferation and the deposit of fatty substances within the epithelial cells, and finally the stage of atrophy and scar formation.

When two such common disorders as nephritis and portal cirrhosis are so comparable in their course, one must ponder whether there are not common etiologic factors. In both diseases alcohol and nutritional deficiencies may play an important part in individual cases, but in the one no more than the other does the time seem ripe to attach specific etiologic significance to either of these influences.

In the case of portal cirrhosis, alcohol as well as chronic infection, toxemia, disturbances of metabolism, tissue susceptibility and, no doubt, central nervous system influences, such as seem to occur in hepatolenticular degeneration, all play their role in the causation of the disease. In the light of our present knowledge, the disease might well be regarded as not essentially due to alcohol or any other known specific factor.

---

[11] Karsner, H. T.: Morphology and Pathogenesis of Hepatic Cirrhosis, Am. J. Clin. Path. **13:** 569-606 (Nov.) 1943.

It would be unfortunate for the lay person to gain the impression that alcohol is blameless in the development of cirrhosis. Certainly it must be much to blame in given subjects. This being the case, it would behoove the members of the medical profession to discourage recent attempts to minimize the importance of alcohol as, if not a specific factor, at least a contributing or predisposing factor in the development of cirrhosis of the liver.

Finally, considering the nonspecific status of alcohol, the suggestion is made again, in the interest of scientific accuracy, that all reference to any type of cirrhosis as "alcoholic cirrhosis" be abandoned.

NEW METHODS OF THERAPY IN CIRRHOSIS OF THE LIVER

LESTER M MORRISON, M D.
Los Angeles

Cirrhosis of the liver is no longer a hopeless, incurable disease destined to progress until death intervenes. Recent reports[1] are rapidly accumulating evidence which shows that many patients with hepatic cirrhosis can improve, or recover as judged by clinical observations and laboratory tests, after treatment by the Patek regimen,[1a, b] with choline or with choline and cystine.[1i] I have reported elsewhere a detailed analysis of the results of treatment in cirrhosis of the liver in a series of 62 patients studied at two year intervals[1j] over an eight year period of time. In this present paper the results and basis for the treatment of choice in cirrhosis are described and offered for trial by others.

METHODS OF TREATMENT

The treatment which I have adopted consists in the administration of methionine, 2 Gm. daily; choline chloride, 2 Gm. daily, a special liver extract prepared by the filtration and concentration of an aqueous liver solution containing vitamin B complex; a high protein (higher than heretofore advocated), low fat, moderate carbohydrate diet and frequent feedings of skimmed milk. To my knowledge this identical combination has not previously been reported for human cirrhosis of the liver, and its adoption is based on experimental and clinical evidence.[2]

This therapeutic regimen was adopted for two reasons: first, as is now well known, the experimental evidence obtained in animals indicates conclusively that choline and methionine are proven lipotropic agents in the prevention and alleviation of fatty cirrhosis of the liver in the experimental animal. The experimental evidence that has been amassed in cirrhosis of the liver and in cirrhosis due to alcoholism in human subjects indicates that cirrhosis is a form of nutritional deficiency disease, or, more specifically, a labile methyl-group deficiency disease.[3] It is also possible that cirrhosis of the liver may be due to a specific vitamin deficiency, just as the macrocytic anemia of pernicious anemia and sprue appears now to respond specifically to folic acid therapy.[4]

Conflicting results were obtained with synthetic cystine, some investigators reporting lipotropic activity of cystine[5] and others reporting its cirrhosis-producing effect.[6] For this reason, synthetic cystine was not employed in this series of cases.

It has been suggested that the lipotropic agent methionine could enhance in a synergistic way the lipotropic (or fatty-cirrhosis-preventing) activity of choline.[7] Animal experiments revealed further that in hepatic damage choline would largely prevent the cirrhosis but not the necrosis and hemorrhage. Methionine was found to effectively prevent both types of damage to the liver. Experimental studies also showed that the cirrhotic symptoms due to choline deficiency result from lack of a methyl-containing essential other than choline and that methionine can directly supply this lack.[8] It is now apparent that although diets may contain an adequate supply of choline, an imbalance or deficiency of other dietary constituents can nullify the lipotropic action of the choline.[9]

Experimental studies demonstrated that an inadequate level of methionine cannot be compensated for

by excessive levels of choline and cystine.[10] It was further demonstrated that when methionine was added to choline in experimental hepatic damage and growth, a 50 per cent improvement in therapeutic results occurred.[10b] The damaged liver thus appears to have lost its transmethylation ability and requires both synthetic methionine and choline until normal transmethylation can take place from the ingested food.

Second, in a controlled series of 62 patients over an eight year period,[1j] therapeutic results suggested that the combination of methionine and choline resulted in a better therapeutic response than did various other combinations of amino acids, diet, liver and vitamin supplements in the treatment of hepatic cirrhosis. Methionine was taken orally in capsule form, the dosage being 2 Gm. daily. Similarly, choline chloride was administered orally in a daily dosage of 2 Gm.[10d]

A special liver extract was used by me because of experimental evidence that indicated its importance, when used with choline derivatives, as an aid in the prevention of hepatic damage.[11] In addition, clinical evidence showed that a crude liver extract has definite therapeutic value in the treatment of human cirrhosis of the liver.[1a, h] I used a specially filtered liver extract [11a] fortified with vitamin B complex, the administration of which was relatively painless, thus allowing large quantities (3 to 5 cc.) to be injected intramuscularly daily, or every other day, for periods varying from several weeks to several months; injections were tapered off to twice or once a week depending on clinical and laboratory progress in each case. Total vitamin supplements in the diet were often used for the same reasons, which demonstrated their experimental and clinical value in cirrhosis.[12] Each cubic centimeter of the vitamin B complex incorporated in the liver extract contained 10 mg. of thiamine chloride, 10 mg. of nicotinamide and 0.3 mg. of riboflavin. It is possible that the liver extract or the vitamin B complex contains a catalytic agent, which permits transmethylation and utilization by the liver of methionine and choline. In support of this suggestion is the experimental evidence that although the choline and methionine content in the cirrhotic liver may be normal or actually higher than normal,[8a] these factors are not available for utilization.

The high protein diet which I prescribed consisted not only of a high casein source of proteins by the use of skimmed milk feedings and cottage cheese but also of servings of meat three times a day wherever possible. The importance of a high protein diet in cirrhosis of the liver is now thoroughly established [13] and takes precedence over dietary carbohydrate in therapeutic importance. The maximum use of meat in this diet appeared to be advisable because of the necessity for providing the essential amino acids which contain the basic methyl groups, with and without the sulfur radical. These methyl groups are required by the liver for the transmethylation function which institutes regeneration and healing in cirrhosis. As has previously been stated, cirrhosis of the liver when produced experimentally is now regarded as a methyl-group deficiency disease.

In all possible ways, in cases in which the patient could tolerate it, the patient's diet was stepped up to the limits of tolerance by forced feedings, or any other device, in the attempt to ingest the ideal maximum intake of 200 to 300 Gm. of protein, 300 Gm. of carbohydrate and 50 Gm. of fat.

CLINICAL MATERIAL

A group of 20 patients with proved cirrhosis of the liver were treated and diagnostically divided into (*a*) 9 patients with ascites and (*b*) 11 patients apparently free of ascites. All 20 patients revealed characteristic physical signs of cirrhosis of the liver, such as palpable enlargement of the liver, increased venous circulation in the skin over the anterior part of the abdomen and upper portion of the chest, ascites, edema of the legs, glossitis and decided loss of weight. In addition characteristic symptoms were present, such as weakness, malaise, inability to engage in normal mental or physical activities, anorexia or nausea, abdominal distress, gas, belching and constipation.

There were 16 men and 4 women in this group. Nine patients gave an antecedent history of alcoholism. The ages ranged from 36 to 64 years, with a group average of 50 years. The average duration of symptoms on presentation for treatment in the group was 1.6 years, with a range of from one month to five years.

For comparison a control group of 23 patients with cirrhosis of the liver was analyzed. This group of patients was treated from 1938 to 1940 by the therapeutic regimen then in current use; a high carbohydrate diet, palliatives, dextrose given intravenously, sedatives and diuretics. The average duration of symptoms before treatment was 1.8 years, with a range of from one month to 5 years. Twelve of these patients were chronic alcoholic addicts, and their average age was 46 years.

Improvement was measured both in clinical terms, such as decrease in the size of the liver, increase in strength and appetite and amelioration of preexisting symptoms, together with improvement toward normal values in liver function tests. The liver function tests routinely used in almost every case were the intravenous sulfobromophthalein sodium excretion test (thirty and sixty minute samples), the urobilinogen test in twenty-four hour specimens of urine, the icterus index and quantitative van den Bergh tests from the blood and bile salt concentration tests of the bile and urine devised by me.[14] Many additional tests were performed, such as the cholesterol ester partition value and the hippuric acid synthesis test. The tests were carried out immediately prior to treatment, and frequent periodic checks were made, usually at monthly intervals.

The tests involving only urinary excretions were often made more frequently. It was usually possible to correlate the tests with clinical improvement, although this could not be done in numerous instances due to contradictory results. However, more often than not laboratory correlation between the tests occurred, even though differing tests examined different functions of the liver. On the whole, the tests were found to be a valuable index of clinical improvement when clinically interpreted in the knowledge of their limitations and usefulness.

Table 1.—*Cirrhosis of the Liver Without Ascites*

Comparison of control cases* with treated cases† at the end of two years

	Controls *	Treated †
Number of cases	11	9
Deaths	3	0
Incapacitated from illness	6	3
Return to normal activity	2	6
Disappearance of symptoms	1	7
Improvement in liver function tests	1	9
Alcoholic history	6	4

* Patients treated from 1938 to 1940 with palliatives, high carbohydrate diet, sedatives, diuretics and intravenous dextrose.

† Patients treated from 1943 to 1945 with methionine, choline, high protein, low fat diet, liver extract and vitamin therapy.

RESULTS

1. *Group of Nine Patients Without Ascites* (table 1).—After an average of three months of treatment, 8 patients returned to normal activity. The liver in each of these instances receded to normal limits, with the exception of 1 case. Definite clinical improvement was present in each treated case, with complete disappearance of symptoms in 7 cases and improvement in the remaining 2 cases. Liver function tests were improved in each case from two to four weeks after therapeutic management was instituted. Most of the tests were normal in the 7 cases at the end of five months. A control group of 11 patients with cirrhosis of the liver in whom only palliative measures were employed from 1938 to 1940 revealed 3 deaths at the end of three years. The group of patients treated by the methionine-choline liver extract method revealed no mortality at the end of two years. In the control group of 11 patients the morbidity was revealed as 9 patients who had not yet died at the end of two years but were incapacitated because of illness. In the treated group there were no patients who were disabled at the end of two years.

2. *Group of Nine Patients with Ascites* (table 2).—After an average of four months of treatment, 4 patients returned to normal activity. The livers in these 4 patients receded to normal limits in each case. Complete disappearance of symptoms took place in 4 cases, improvement was present in 5 cases. In 4 patients the disease appeared to be arrested, neither improvement nor progression of the disease occurring. One patient grew worse and died after two months. Liver function tests showed improvement in 5 patients, usually in from two to four weeks after therapy. In the untreated control group of cases, 9 of the 12 patients were dead at the end of two years, as against 1 of the 9 patients in the treated group. In the control group the morbidity incidence was 2 patients who survived but were incapacitated at the end of two years, as against 5 patients in the treated group who survived but were incapacitated.

REPORT OF CASES

Case 1.—*History.*—T. I., a white man aged 54, complained of slight jaundice, dyspnea, decided anorexia and nausea, all of three months' duration. The past medical history revealed an intake of about a half pint of whisky and several bottles of beer daily over a ten year period. Meals were frequently omitted.

Physical Examination.—Essentially a mild but definite icteroid discoloration was present in the scleras and skin. The nutritional appearance seemed normal. The abdomen was not distended, and ascites were not detectable. The liver was enlarged to 3 cm. below the right costal margin, and the liver edge was firm, smooth and tender to palpation.

Liver Function Tests.—The icterus index was 28 units; a twenty-four hour urobilinogen test was positive in a 1:60 dilution; the sulfobromophthalein sodium retention in the blood was 15 per cent at one hour. Bile salt concentration tests (Morrison[14]) revealed 620 mg. of bile salts per hundred cubic centimeters of urine and 280 mg. of bile salts per hundred cubic centimeters of bile (both pathologic).

Treatment.—Two grams each of methionine and choline were given daily in conjunction with 3 cc. of an aqueous liver extract fortified with vitamin B complex for two months. The diet consisted of one average serving of meat with each meal, three times a day; a liberal intake of fruit and vegetables, and skimmed milk between each meal and on retiring.

Progress.—Within two weeks there was a diminution in jaundice, an increase in strength and well-being and disappearance of all symptoms. In two months, all visible jaundice had disappeared and the patient was completely free of symptoms. The values for all liver function tests had returned to normal. The edge of the liver had receded and was about 1 cm. below the right costal margin.

This patient was referred for psychiatric treatment in the attempt to prevent recurrence of the emotional factors which had motivated his escape into alcoholism. For one year following his recovery he has remained in excellent physical and mental health.

Case 2.—*History.*—A. L., a man aged 51, a traveling salesman, was seen four months after the onset of jaundice. There was associated weakness, abdominal distention, pain in the epigastrium and loss of weight. From four to five whisky highballs and several bottles of beer had been drunk daily for many years, and meals were frequently skipped when he was driving on long trips. Immediately prior to the onset of jaundice, the patient had been inhaling the fumes from a special antifreeze mixture, which had been escaping from an overheated radiator while he was driving his automobile on long trips.

Table 2.—*Cirrhosis of the Liver with Ascites*

Comparison of control cases* with treated cases† at the end of two years

	Controls *	Treated †
Number of cases	12	9
Deaths	9	1
Incapacitated from illness	2	5
Return to normal activity	1	4
Disappearance of symptoms	0	4
Improvement in liver function tests	1	5
Alcoholic history	6	5

* Patients treated from 1938 to 1940 with palliatives, high carbohydrate diet, sedatives, diuretics and intravenous dextrose.

† Patients treated from 1943 to 1945 with methionine, choline, high protein, low fat diet, liver extract and vitamin therapy.

Physical Examination.—Evidence of loss of weight was pronounced; pitting edema was present in both legs; the abdomen was moderately distended and displayed shifting dulness with a fluid wave. The collateral venous circulation was clearly visible over the abdomen and lower part of the chest; well defined hemorrhoids were present. The liver could not be palpated because of the distention.

Liver Function Tests.—The icterus index was 40 units; twenty-four hour urobilinogen tests were positive in a 1:100 dilution; the sulfobromophthalein sodium retention in the blood was 25 per cent in one hour. Bile salt concentration tests revealed 940 mg. of bile salts per hundred cubic centimeters of urine and 220 mg. of bile salts per hundred cubic centimeters of bile (pathologic). The total serum protein was 6.75 Gm. per hundred cubic centimeters, the albumin-globulin ratio was 0.8.

Treatment.—This patient was placed on a protein diet as high as could be tolerated (three servings of meat a day), low in fat, high in carbohydrate, high in fruit and vegetable content, with 2 quarts (2.3 liters) of skimmed milk and one serving of cottage cheese daily. Two multivitamin capsules[15] were taken daily; 5 cc. of whole aqueous liver extract was injected intramuscularly daily for one week, then every other day for two weeks, then twice weekly for one month. Two grams each of methionine and choline chloride were taken daily for three months.

Progress.—Within two weeks, decided diuresis began; in two months a negative water balance was present, all evidence of ascites and edema having completely disappeared. The edge of the liver was then just palpable below the right costal margin. In three months all tests of hepatic function had returned to normal values, as well as the serum albumin-globulin ratio (1.9). The patient returned to work and was completely symptom-free; one year later he reported that he was in excellent health.

This patient, who had an alcoholic background, probably suffered a superimposed toxic hepatitis when he *inhaled the toxic fumes of an antifreeze preparation* for a one week period while driving his automobile. His ascites responded promptly by diureses, which were due probably to an antidiuretic factor in the treatment as proposed by various investigators.[1c, g]

SUMMARY

1. A group of 20 patients with cirrhosis of the liver was treated by an intensive combined therapeutic regimen from 1943 to 1945; the results were compared with those in a control series of 23 patients with cirrhosis of the liver observed from 1938 to 1940. The control patients did not receive any of the forms of treatment given to those in the treated group.

2. All 43 patients were separated into groups with and without evidence of portal decompensation or ascites. Therapeutic results were compared over two year periods of time in each group.

3. The treatment consisted of the daily ingestion of 2 Gm. each of methionine and choline chloride, an aqueous whole liver extract with vitamin B complex supplement administered parenterally each day and a diet of maximal protein-carbohydrate, minimal fat intake with casein supplements.

4. After two years all patients in the treated group without ascites were alive, as compared with 3 deaths in the 11 patients of the control series.

5. After two years 8 of the 9 treated patients with ascites were alive, as compared with 3 of the 12 in the control series.

6. Six of the 9 treated patients without ascites had returned to normal activity in two years, as compared to 2 of the 11 in the control group.

7. Four of the 9 treated patients with ascites had returned to normal activity in two years, as compared with 2 of the 12 patients in the control series.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. WEIR, DR. OSGOOD, DRS. GIANSIRACUSA AND ALTHAUSEN, DR. CAPPS, CAPTAIN SBOROV AND DR. BARKER, DR. WILBUR, DR. HAVENS, LIEUTENANT COLONEL MALLORY, DRS. KIMBALL, CHAPPLE AND SANES, DR. HOFFBAUER, DRS. BOLES, CREW AND DUNBAR *AND DR. MORRISON*

DR. CECIL J. WATSON, Minneapolis: I want to congratulate not only the contributors to this symposium but also the officers of the Sections, who planned it. With regard to liver function tests, the two methods which are sufficiently simple that they may be designated as bedside tests should be emphasized. These are (1) the urine Ehrlich test for urobilinogen; and (2) the modified Harrison or barium filter strip test for bilirubin. It has been proved that one cannot rely on any single test or, in fact, on any two tests to give the necessary information from case to case. A composite study must be made of the functions of the liver; one must take a vote of these functions, if you will, and in that way, try to get a better insight into the overall current activity of the liver. Dr. Osgood has already indicated this in his excellent article. I think the urobilinogen test in the urine has received some injustice at the hands of dilution technics which have been widely employed. The test of Wallace and Diamond requires evident color in a dilution of 1:20 in order to be regarded as positive. This eliminates a large number of significant reactions. The use of sodium acetate in the qualitative reaction serves to bring out the maximum intensity of color and to eliminate certain interfering colors. I would recommend the inclusion of sodium acetate in this reaction. Dr. Osgood has indicated that the methylene blue test for bilirubin in the urine is simpler but not as reliable as the modified Harrison test. In my experience the latter has been not only simpler but more specific than the methylene blue test; it lends itself admirably to mass usage and is of particular value in the study of a large number of persons with respect to incipient or preicteric hepatitis. In a dynamic disease such as hepatitis, different tests are of different value at various stages of the disease. The experience gained during the war indicates that in the incipient or preicteric stage of hepatitis a study of the prompt reacting serum bilirubin, the urine bilirubin, and the urine Ehrlich reaction permits one to obtain the necessary information in at least a large majority of the cases. In the icteric stage of the disease the Hanger cephalin cholesterol flocculation and the Maclagan thymol turbidity tests, the serum cholesterol, both free and ester fractions, and the urine Ehrlich reaction followed frequently have been of greatest value. In the late, defervescent stage, which offers the greatest difficulty with particular reference to whether the person has actually a latent disease and whether he should be allowed to resume routine activity, one often has to go into more complex and composite types of study. The procedures which have been used to best advantage in this stage are as follows: The serum bilirubin, especially the delayed type, that obtained by subtracting the prompt or 1' fraction from the total; the urine Ehrlich reaction; the Hanger and Maclagan tests; the sulfobromophthalein sodium retention at forty-five minutes after the injection of 5 mg. of the drug per kilogram of body weight; and finally, the twenty-four hour urinary coproporphyrin which appears to be one of the most delicate means of detecting residual hepatic functional impairment.

DR. S. J. GLASS, Los Angeles: This symposium would be incomplete without proper emphasis of one of the functions which, in my way of thinking, is extremely important to reproductive physiology; namely, that one concerned with the inactivation of the sex steroid hormones. There is now ample experimental and clinical evidence, to indicate that a damaged liver will invariably be followed by some damage of the reproductive organs, particularly the testes and the sex accessories. This is probably due to the hepatic failure of steroid hormone inactivation, particularly the estrogens, so that abnormal concentrations of free, biologically active estrogens are available for the induction of gonadal damage, especially in the male. The damage to the sex organs is, in my experience, proportional to the severity and the duration of the hepatic disease. My associates and I reported in 1940 such hormonal observations in the striking syndrome of gynecomastia and testicular atrophy associated with advanced hepatic cirrhosis. Recently our group observed damage of sex organs in rats with experimental cirrhosis. Apropos of this liver-gonadal relationship, Snell and his associates reported in 1945 striking testicular damage in cases with acute hepatitis. Wood in 1946 likewise reported testicular damage in men with acute hepatitis. It is necessary to emphasize this liver-gonadal relationship so that a closer inspection of the patient be made at the bedside as well as at the postmortem table for evidences of pathologic conditions of the reproductive system particularly in the male testes, in the sex accessories and in the breast, in every case of disease of the liver. Where facilities are available, hormone assays for the estimation of urinary estrogens should be carried because the presence of free unconjugated estrogens in the urine is, in our experience, an accurate index of the failure of that particular function of the liver which has to do with the inactivation of the sex steroids. The clinical implications of this particular liver-gonadal relationship are truly legion. I commend their consideration to this group.

---

[15] Capsules contained vitamin A 5,000 units, vitamin B_1 3 mg., vitamin B_2 2 mg., vitamin B_6 1 mg., calcium pantothenate 1 mg., niacinamide 20 mg., ascorbic acid 30 mg. and vitamin D 500 international units.

DR. LEON SCHIFF, Cincinnati: I should like to reemphasize the value and practical aspects of hepatic biopsy. At Cincinnati needle biopsy of the liver has been performed in 75 patients, and has been found particularly helpful in the diagnosis of hepatoma and secondary malignant disease of the liver. It was particularly useful in diagnosis in the case of a woman aged 32 who was admitted to the Cincinnati General Hospital with deep jaundice and coma; a clinical diagnosis of acute yellow atrophy was made by the clinicians who saw her. Biopsy of the liver revealed the changes of early obstructive cirrhosis. Two months after the patient recovered from coma and jaundice, laparotomy was performed and a stone was removed from the common duct. A hepatic biopsy specimen obtained at operation still showed the presence of obstructive cirrhosis, but a year later a third biopsy of the liver showed complete restoration of the organ to normal. We have had no serious mishaps in our 75 patients, although, as Dr. Hoffbauer has stated, fatalities have been reported subsequent to the procedure. Recently we encountered an instance of perihepatitis about two weeks after the procedure was carried out, with the perihepatic friction persisting for another week. I should like to ask Dr. Hoffbauer if he has encountered this complication. I should also like to ask if he has used the procedure in the differential diagnosis of jaundice due to hepatitis and that due to tumor or stone in the common duct. Since histologic studies have recently been made in infectious hepatitis, it seems that acquaintance with these changes might be helpful in the differentiation of this disease from jaundice due to neoplasm or to stone in the common duct. I should like to ask Dr. Althausen if he noticed any differences in the intravenous galactose tolerance and response of prothrombin time to vitamin K between the so-called hepatocellular group of hepatitis and the group Dr. Watson has referred to as the cholangiolar type. I believe a fourth of his cases were of the cholangiolar type. I should also like to ask Captain Sborov if he and Drs. Capp and Barker have a practical application of the exercise tolerance test in patients with infectious hepatitis which might be used in civilian practice.

DR. THEODORE L. ALTHAUSEN, San Francisco: I wish to say a few words about the first two papers on the program, those by Drs. Weir and Osgood. The merit of needle biopsies of the liver has interested me but the mortality associated with this diagnostic procedure, even though small, has prevented me and my associates from using it. In reference to Dr. Kimball's remarks about the reduced mortality rate of hepatic cirrhosis during the last five years I want to say that with the beginning of the war a decided drop in admissions of patients with cirrhosis and a reduction in the mortality rate of this disease has been observed at the San Francisco County Hospital. This has not occurred at the University Hospital. A possible interpretation of this difference is that before the war patients with cirrhosis who were admitted to the County Hospital had been able to raise enough money for liquor but had little left over for food. Since the beginning of the war they had enough money for both, with a corresponding improvement in their health. At the University Hospital, where patients from a higher economic level are represented, no such change was observed. To answer Dr. Schiff's question, no difference was noticed in the results of the intravenous galactose test or in the response of prothrombin time to vitamin K administration in the two types of hepatitis which he mentioned.

DR. HARRY SHAY, Philadelphia: I should like to stress the value to be derived from liver function studies in the differentiation of hepatocellular and cholangiolar or other types of obstructive jaundice. In evaluation of liver function tests, especially in jaundice, certain factors must be kept in mind. The multiplicity of the functions of the liver and the dissociation of the effects produced by hepatic damage has been stressed adequately. Another factor mentioned by Dr. Watson has not been appreciated sufficiently, namely that hepatic function is always a dynamic never a static process, and especially so in jaundice. In testing liver function in jaundice, several tests performed early and repeated frequently will overcome these difficulties. An adequate procedure should include two tests primarily affected by obstruction and two by hepatocellular damage. These requirements are met by the cholesterol partition in the blood serum, serum alkaline phosphatase and thymol turbidity tests. The quantitative van den Bergh measures the level of icterus. Total serum cholesterol and phosphatase reflect the effects of obstruction, while cholesterol ester ratio and thymol turbidity tests reflect those resulting from hepatocellular damage. Serum alkaline phosphatase was found to be the most sensitive indicator of obstruction. Striking changes in serum phosphatase levels occur with little or even no alteration in bilirubin level under conditions which cause only slight back pressure in the biliary tree. From a study of the various flocculation tests, the cephalin cholesterol, colloidal gold and thymol turbidity tests, I believe the last named will prove to be the most useful in the differentiation of jaundice. I have been impressed by a persistence of precipitate in the thymol test at eighteen hours in acute hepatitis after return of the reading of the test to normal at one-half hour. I have attempted to quantitate the precipitate by reading the turbidity of the supernatant at the end of eighteen hours. This reading in Maclagen units as the numerator over the half hour reading as denominator establishes a ratio indicating the degree of precipitation. Extremely interesting curves of these ratios can be plotted in the recovery and convalescent periods of patients with acute hepatitis. In my opinion the persistence of such precipitates into the convalescent period is not indicative of continuing hepatic damage provided the ratio continues to approach 100 per cent. Its persistence seems an indication of the time necessary for the serum protein fractions to become completely normal after acute hepatitis. The failure of the ratio to approach 100 per cent may be an indication of continuing damage to the liver even when other liver function tests have returned to normal.

DR. HYMAN I. GOLDSTEIN, Camden, N. J.: I rise to discuss the presentations by Drs. Althausen, Wilbur, Boles and Morrison. In reviewing the modern methods of diagnosis and treatment of hepatic disease, particularly that associated with jaundice, macrocytic anemia, alcoholic cirrhosis, hepatitis and neoplasm of the liver one should recall the early work of the Frenchman Professor Maurice Perrin of Nancy and others of his countrymen. I knew Professor Perrin, and I was on the programs at Vichy, France, in 1932 and in 1937, where I met him while attending the International Congresses on Gallbladder and Liver Diseases. Professor Perrin in 1904, 1905 and 1908 published his reports on "Alcoholic Cirrhosis." He found that liver therapy improved the anemia and the general condition of his patients. In June 1921 I published a paper on "Primary Sarcoma of the Liver" (Internat. Clinics 2:73 [June] 1921) with a Review of the Literature and the report of a case. Fifty-nine cases (primary) were found recorded in the literature (1921). Many of them were associated with cirrhosis or with gallstones. Few, if any, occurred in alcoholic addicts. MacMahon, Murphy and Bates, of Boston, on June 19, 1946 reported a case of primary sarcoma of the liver which in their opinion was caused by the administration of colloidal thorium dioxide for roentgenologic diagnosis and study. This interesting report was presented before the National Gastroenterological Association in New York. In my paper on "Primary Malignant Tumors of the Liver," (*M. J. & Record* **120**:119-123 [Aug. 6] 1924), with report of 12 cases, it was shown that cirrhosis and cancer may coexist without causal relationship (Yeomans). Cirrhosis may precede or follow the growth. However, in Eggel's series some cirrhosis was present in 85.4 per cent. In 69 of 163 cases pronounced cirrhosis was present.

Dr. Leo Lowbeer, Tulsa, Okla.: I should like to bring to your attention another cause for cirrhosis of the liver, namely chronic brucellotic infection. It is known that brucellotic granulomas frequently occur in the liver of inoculated animals. They have also been frequently found in livers of patients with fatal brucellosis at autopsy. I had occasion to biopsy the liver of a patient with osteomyelitis of the ilium bacteriologically proved due to Brucella suis. In this patient there developed symptoms of a cholecystitis, and the surgically removed gallbladder as well as a biopsy of the liver contained a large number of brucellotic granulomas. A similar observation on a hepatic biopsy was reported by Mettier and Kerr. In view of the chronicity of the brucellotic process it is conceivable that this often diffuse granulomatous inflammation of the liver may develop into cirrhosis of the liver. As a matter of fact, Hegler, Habs and others have reported cases of bacteriologically or serologically proved brucellotic infection, in which they could observe the development of a hepatic cirrhosis from an early stage with hepatomegaly and jaundice to a terminal stage with ascites and esophageal varicosities. They spoke of a hepatosplenomegalic type of chronic brucellosis. A review of the reported autopsies on fatal cases of brucellosis shows a certain percentage in which cirrhosis of the liver had developed during the brucellotic infection and death was due to rupture of an esophageal varix or to ascites with wasting.

Dr. Virgil H. Moon, *Philadelphia*: A pathologist has a keen interest in the histogenesis of portal cirrhosis. This tempts me to violate the precedent that the chairman should not discuss items on the program. After years of study on portal cirrhosis, often called the alcoholic cirrhosis, I came to the conclusion that from the point of view of pathology portal cirrhosis is synonymous with chronic progressive hepatitis. Hepatitis which does not become chronic and which does not progress, as the cases of acute hepatitis under discussion today, do not qualify as cirrhosis. The causes of chronic progressive hepatitis will be sought and perhaps found among those agents or conditions which singly or in combination will produce a chronic, progressive, inflammatory process. I agree with Dr. Boles that alcohol is not usually a primary agent. I think that he also endorses the belief that alcohol may act as an important contributory factor and hence may fall into the category of combinations of agents, thereby stimulating or increasing the effect of some other agent which is producing injury to the liver, with chronic inflammation as a result.

Dr. Edwin E. Osgood, Portland, Ore.: I agree with Dr. Watson's comments on the relative merits of the liver function tests mentioned in my paper. I want to reemphasize the importance in interpretation of liver function tests of the time-intensity curves which are graphic representation of the stage of the disease, as determined from the history and serial tests.

Dr. Frederick W. Hoffbauer, Minneapolis: Dr. Schiff has raised the question of the development of perihepatitis at the site of needle biopsy of the liver. I do not recall having observed such a reaction. There is always a small amount of bleeding at the site; some such reaction at that area might well occur. It is more difficult to answer Dr. Schiff's second question: can needle biopsy of the liver be used to advantage in the differential diagnosis of the jaundiced patient? In other words, can one determine from the histologic examination of this small strip of tissue whether the jaundice is due to an intrahepatic obstruction, such as occurs in parenchymal disorders, or is due to the intrahepatic obstruction of a gallstone, a tumor or a stricture of the biliary ducts? I directed this same question to Dr. Iversen of Copenhagen, Denmark, recently. On the basis of his wide experience of over 600 biopsies, Dr. Iversen is in a much better position to judge the value of the procedure in this regard. He stated in his letter that if the patient was subjected to biopsy within the first two weeks of jaundice, one could nearly always differentiate the nature of the obstructive process. This is certainly in keeping with my experience which has been on a much smaller scale. It must be admitted that the strip of tissue is extremely small, and the pathologist may well experience difficulty in interpretation if the specimen for biopsy is taken weeks or months after the onset of jaundice.

Capt. Victor M. Sborov, M. C., A. U. S.: In answer to Dr. Schiff's question about a practical exercise tolerance test, I should like to say that prior to the time the patient is given his exercise tolerance test other criteria for cure must be met. The patient must have completed at least four to six weeks of strict rest in bed and should be completely free of symptoms. There should be present no clinical symptoms, no enlargement of the liver or hepatic tenderness. The last mentioned is the most important. The laboratory tests should be completely within normal limits. Following this the patient is allowed to become slowly ambulatory on the ward over a period of seven to ten days, and if the criteria for cure continue to be met the patient is then allowed to take the exercise tolerance test. In the service I admit that the exercise tolerance test is a lot easier to execute than in civilian practice. There the patient is guided by the reconditioning officer. The first day the test consists merely of a 1 mile hike, the second day a 2 mile hike plus fifteen minutes of calisthenics, the third day a 3 mile hike plus 20 minutes of calisthenics, and so forth, until ten to fifteen days have been completed; the calisthenics consist preferably of liver-jolting exercises, such as a side straddle hop. The civilian patient cannot be followed as easily as the man in the service; however, the exercise test is important, I believe, and should not be overlooked. Its practical execution depends on the ingenuity of the physician. I think such exercises as horseback riding or long walks can easily be performed by the patient. To facilitate the following of the patient by the physician, the patient can be instructed as to the symptoms which will predict a relapse, such as discomfort in the right upper quadrant of the abdomen, flatulence and the other characteristic complaints.

Dr. Tracy B. Mallory, *Boston*: Dr. Watson is going to force me to mention something which I carefully left out, since I consider available evidence inadequate. In all the postmortem material which had been submitted to the Army Institute of Pathology up to the first of December, there was not 1 definite case of cirrhosis which could be attributed to a preceding hepatitis. In the biopsy material the time interval, as Dr. Watson pointed out, was invariably short. Since these cases were studied in an active theater of war, if a man was not able to get back to duty in the course of three or four months he was sent home, so there was no opportunity to observe late cases. In the group were 2 cases which seemed to be cirrhotic. One patient had no characteristic acute attack and the impression was gained that he had a mild cirrhosis before entering the Army. The second patient did have acute hepatitis and two months later showed early fibrosis; on the other hand, all these biopsies were obtained by the peritoneoscope and the possibility of extension of fibrous tissue from the capsule was difficult to exclude. In civilian life I have seen a number of cases of what F. B. Mallory in 1905 called toxic cirrhosis following hepatitis. These patients have survived considerable periods, in 1 instance as long as ten years after the initial episode. Ascites developed, and they required repeated hematemeses, showed enlarged spleens and had all the common symptoms of cirrhosis of the liver. I believe that it is probable that in occasional incidences cirrhosis of this type does follow epidemic hepatitis.

Dr. Stockton Kimball, Buffalo: I merely want to comment on Dr. Althausen's remarks. In my second five-year group of cases occurring during the war, the incidence of cirrhosis was greater than was that of alcoholism; the incidence of avitaminosis and of jaundice was greater than in the previous period.

Dr. Russell S. Boles, Philadelphia: In lieu of accepting your apology, Mr. Chairman, I think we would have to criticize you for shirking your responsibility had you not taken part in this discussion. Dr. Moon is one of the great authorities on this subject. My main purpose is to sound a note of caution against drawing too hasty conclusions and assuming that this disease, portal cirrhosis of the liver, is a disease due to nutritional deficiency. I am hearing that more and more every day, from the students at Philadelphia General Hospital and from interns and physicians. Personally I don't believe it is any more a nutritional deficiency disease than a disease solely due to alcoholism; on the other hand, I want to commend Drs. Morrison, Nemling and Neal as well as many others for the interesting, constructive work they are doing in the treatment of this disease. However, I believe their results are being best achieved in those cases showing fatty dystrophy of the liver in which some degree of reversibility can be attained. In the later stages of portal cirrhosis, when extensive scar formation has taken place and ascites has developed, it is not conceivable to me that parenchymal regeneration can occur, the symptoms subside and the disease be cured or even arrested. I do not believe these patients could grow new liver cells any more than they could grow hairs on a bald head. I can't follow the logic as far as protein is concerned. It was not long ago when it was reported that an excessive degree of animal protein was injurious to the liver. I appreciate that protein in acute disease conditions hastens the regeneration and proliferation of tissue. If a drunk eats an excess of anything, it is protein. He often lives on meat and potatoes. Economics, as Dr. Althausen has pointed out, has little to do with this disease in the East. In a large, 2,500 bed hospital, such as the Philadelphia General, one picks up a considerable knowledge during the years concerning the diet of this class of people. It is the wealthy patients who often show the least intelligence about their diet and who might be more susceptible to these diseases, if diet alone was so much to blame. There is some great unknown factor at work in the etiology of cirrhosis. No one knows why some particular person is going to become an alcoholic addict. Of 10 persons drinking the same amount of alcohol over the same period, some 1 or 2 are doomed to alcoholism. Why? Is it a constitutional predisposition, or tissue susceptibility? No one knows. The same thing with cirrhosis. There may be 100 individuals drinking the same amount of liquor over the same period, and some 1 or 2 of them are going to get cirrhosis. Why?

Dr. Lester M. Morrison, Los Angeles: I wish to thank Dr. Watson for his comments. I would like to emphasize that the best results occur in the treatment of alcoholic cirrhosis; and of these, the best results are obtained in the patients in whom the cirrhosis or the cirrhotic ascites has developed comparatively recently. This may account for the difference in therapeutic results in Dr. Watson's cases, since his etiologic incidence of alcoholism is half that in my cases. He also feels that the methionine content in the high protein diet is such (3 Gm.) as to render unnecessary the administration of synthetic methionine. Bollman, Mann and Magath first showed, by their classic experiments on hepatectomized dogs, that the metabolism of amino acids and the process of deaminization takes place mainly in the liver. I feel that these functions are so impaired in the cases of cirrhosis which I have presented that the liver is unable to metabolize sufficiently for the patient's needs the methionine in the diet. Therefore, until this point is clarified exactly I would prefer to give the methionine and to make certain that the patient receives an adequate supply of methionine. I believe the experimental work on methionine which I have quoted tends to support this belief. I also wish to thank Dr. Boles and Dr. Goldstein for their comments.

STREPTOMYCIN TOXICITY

Reactions to Highly Purified Drug on Long-Continued Administration to Human Subjects

ROBERT F. FARRINGTON, M.D.
HARRIET HULL-SMITH, M.D.
PAUL A. BUNN, M.D.
and
WALSH McDERMOTT, M.D.
New York

It is probable that the principal value of streptomycin will be in the treatment of subacute and chronic infections, notably tuberculosis, in which it will be necessary to administer the drug for long periods. Evaluation of the chronic toxicity of the material for human beings is thus appreciably more important than is the case with sulfonamide compounds or penicillin.

The effects of the short term administration of preparations of impure streptomycin to human subjects have been studied both by a number of independent investigators and in a cooperative study under the auspices of the National Research Council.[1] The only observations on long-continued administration of impure streptomycin are those presented in a preliminary report by Hinshaw and Feldman.[2] In their study an average daily dose of 1.5 Gm. of the drug was administered for periods of several or more months. In all the reports there is agreement that in general the impure drug is well tolerated but that occasionally untoward reactions of variable severity occur.

Four general types of toxic reaction have been observed: the so-called histamine reaction, characterized by flushing, headache and an abrupt fall in arterial pressure; various manifestations of anaphylaxis; a neurologic disturbance characterized by vestibular dysfunction and occasionally by deafness,[3] and evidences of renal irritation manifested by cylindruria and occasionally accompanied by impairment of renal function.[4]

It has not been possible to establish whether the observed evidences of toxicity were caused by contaminating substances or were produced by the antibacterial agent itself. There is reason to believe that at least one phenomenon, the so-called histamine reaction, was the

---

The study was also aided in part by a grant from the Lederle Laboratories, Inc., Pearl River, N. Y.

A part of the streptomycin was furnished by the committee, and the remainder was generously donated by Chas. Pfizer & Company, Inc., Brooklyn.

Owing to lack of space, this article has been abbreviated in The Journal by omission of tables 1 and 2. The complete article will appear in the authors' reprints.

This investigation was conducted under the direction of the National Research Council Committee on Chemotherapeutics and Other Agents, Dr. Chester S. Keefer, chairman.

4. Unpublished observations from this laboratory.

result of an impurity, as it occurred only after the administration of certain lots of the drug and is no longer detectable in the currently available product. Molitor and his associates,[5] however, observed evidences of toxicity even after the administration to animals of "chemically pure" streptomycin (800 micrograms streptomycin base per milligram). The "pure" material was free from the "histamine-like" substance but, when administered intravenously to monkeys in daily doses of 25 mg. per kilogram of body weight or higher, produced "a fatty metamorphosis in the liver and, less often, in the kidney." A transient proteinuria developed in 1 animal which had received 200 mg. per kilogram of body weight a day (three to four times the dose used in clinical practice). The hepatic and renal lesions were apparently reversible. In additional experiments in dogs these investigators noted the appearance of albuminuria and cylindruria after ten to fourteen days' treatment with streptomycin (50 or 100 mg. per kilogram of body weight a day), the purity of which was unspecified. A slight degree of tubular necrosis was observed in 1 dog which had shown severe proteinuria. Changes in gait and posture suggestive of a labyrinthine or cerebellar disturbance appeared in 3 of 5 animals. Molitor and his coinvestigators have emphasized that there is a considerable species-variation in tolerance to streptomycin, as rats, mice and guinea pigs showed no significant pathologic changes after the administration of large doses of the drug for periods of several months.

At present, therefore, it appears that (*a*) in order to realize the maximal therapeutic potentialities of streptomycin the drug must be well tolerated on continued administration for several or more months and (*b*) in order to establish the chronic toxicity of the material for man it is desirable to attempt to define the respective roles of the antibacterial substance and the associated impurities.

Accordingly, an investigation has been conducted in a group of human subjects, who underwent a four month period of continuous therapy with highly purified streptomycin sulfate.

MATERIALS AND METHODS

Streptomycin.—Four lots of streptomycin, each consisting of 1 Kg., were used. In general, an individual lot was administered throughout each month of the study. In the preparation of the individual lots, impure streptomycin (approximately 450 micrograms per milligram) was purified and converted to the crystalline calcium chloride double salt. The crystalline salt was then converted by mild treatment to the sulfate to ensure stability. The results of the relevant biologic and chemical analyses, which were performed in the laboratories of Chas. Pfizer & Company, Inc., are presented in table 1.[6] The final product used in the investigation was at least 95 per cent pure. The material was dissolved in 2.0 cc. isotonic solution of sodium chloride prior to injection, and the p_H of the resulting solution was 6.0.

Subjects.—Sixteen adults with active pulmonary or acute hematogenous tuberculosis were the experimental subjects. The group consisted of 4 Negroes, 11 white persons and 1 Chinese. All the subjects were febrile, and some were critically ill at the time of the institution of therapy. In no instance, however, was there any demonstrable evidence of abnormal renal function or tuberculous involvement of the kidneys. Audiometric examinations before treatment revealed abnormal conditions in only 2 subjects. In these persons nerve deafness with a loss of hearing of 9.3 and 12.6 (Co) and 19.3 and 8.8 (Ir) per cent, respectively, was present.

Subsequent to the present study, an additional 15 patients have been treated with this same preparation of streptomycin for periods shorter than one hundred and twenty days. The pertinent observations made in this group are included and separately indicated in the present report.

Technics.—The streptomycin concentrations in the body fluids were determined by the cup plate diffusion method of Stebbins and Robinson, in which Staphylococcus aureus of the S. M. strain is used as the test organism.[7] The urea clearance was calculated according to the formula of Moeller, McIntosh and Van Slyke,[8] and the plasma proteins were measured by the method described by Kingsley.[9] The sulfobromophthalein sodium retention [10] and the thymol turbidity tests [11] were used in the evaluation of hepatic function. Caloric stimulation of the vestibular apparatus was performed by injecting 2.0 cc. of ice water into the external auditory meatus. The reaction was considered to be normal when the time required for the onset of nystagmus was approximately one fourth as long as the duration of nystagmus.[12] All the audiometric examinations were made on a Maico audiometer in a room which is heavily insulated but not completely soundproof.

Protocol of the Investigation.—The subjects remained in bed throughout the period of the investigation and were observed daily for any evidences of drug toxicity. Immediately prior to the institution of streptomycin therapy the status of renal, hepatic, vestibular and auditory functions was determined by the procedures listed in table 2. Subsequent observations were made at the intervals indicated in the table, and complete neurologic examinations were made each week.

Streptomycin Regimen: Three grams of streptomycin (approximately 45 mg. per kilogram of body weight) was given to each subject daily. The total period of therapy was at least one hundred and twenty days, except for 2 subjects who died on the ninety-ninth and ninety-third days, respectively. The material was administered intramuscularly at three hour intervals, in individual doses of 0.375 Gm. The treatment was absolutely continuous in 13 of the 16 subjects. In the remaining 3 the administration of the drug was interrupted for periods of ten, twenty and eighty-six days.

Absorption and Distribution of the Streptomycin: The concentration of streptomycin in the blood at the end of the three hour interval between injections (charts 1 and 2) ranged between 7 and 30 micrograms per cubic centimeter of serum and was usually between 10 and 20 micrograms per cubic centimeter. Two specimens of pericardial fluid and 1 of pleural fluid, obtained after several days of intramuscular administration, contained amounts of streptomycin approximately equal to those present in the subjects' serum (10.1 to 11.5 micrograms per cubic centimeter). There was no detectable streptomycin in specimens of cerebrospinal fluid withdrawn from 5 subjects after several or more weeks of intramuscularly administered therapy. These values are essentially the same as those reported by other investigators after the use of crude streptomycin.[13]

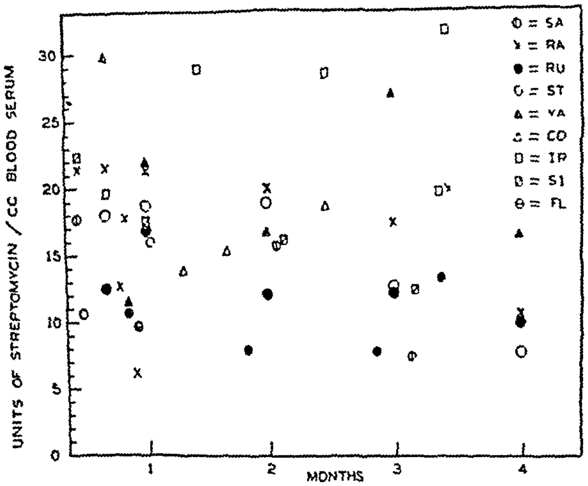

Chart 1.—Serum streptomycin levels. The dosage of 0.375 Gm. was given intramuscularly at three hour intervals. Samples were taken prior to the next three hourly dose.

MANIFESTATIONS OF TOXICITY

Throughout the entire one hundred and twenty day period it was considered advisable to interrupt the therapy of only 2 subjects because of a manifestation of toxicity. In both instances the reactions were anaphylactic in type, and it was possible for both patients to resume treatment subsequently.

Local Irritation.—Despite the administration of the drug at three hour intervals for so long a period, there was remarkably little irritation at the sites of the intramuscular injections. The subjects had all understood that it was planned to terminate the investigation at ninety days. At that time, however, when it was proposed that the investigation be continued for another month, the entire group availed themselves of the opportunity to obtain the additional therapy.

Intrathecal Administration.—Three subjects, who were without evidence of central nervous system disease, were given 0.1 Gm. streptomycin intrathecally dissolved in 10 cc. of isotonic solution of sodium chloride. In 2 of these persons the procedure was well tolerated, and they complained only of a slight headache during the succeeding day. The cerebrospinal fluid cell counts twenty-four hours after the intrathecal injections were 139 and 4 cells per cubic millimeter, respectively. In the third subject the intrathecal administration of the drug was followed by a reaction which was characterized by headache, nausea and vomiting. In this patient the cerebrospinal fluid contained 380 cells per cubic millimeter (95 per cent neutrophils) twenty-four hours after the instillation of the streptomycin. The reaction was complicated by evidences of anaphylaxis, to be discussed subsequently, but the symptoms of meningeal irritation subsided promptly within twenty-four hours.

A fourth subject, who presented minimal evidences of inflammatory disease of the central nervous system, received 0.1 Gm. streptomycin intrathecally in the lumbar region every day for a total period of twenty-eight days. Other than occasional leg pains, which were presumably the result of transient irritation of the nerve roots, the procedure was well tolerated.

Larger amounts of drug (0.2 to 0.375 Gm.) were repeatedly administered by the intrathecal route at forty-eight hour intervals to 6 persons, 5 of whom are not otherwise included in the study. In most instances the 0.2 Gm. dose was well tolerated. Moreover, the 0.375 Gm. dose was also well tolerated in each subject for the first seven to ten days of administration. In some patients among those on each of the two dosage regimens, however, and particularly after the 0.375 Gm. dose had been continued for several weeks, definite evidences of toxicity appeared after the intrathecal injection. The toxic reaction was characterized by somnolence, which at times approached stupor; headache; a slowing of the respiratory rate, and retention of urine. The symptoms usually persisted for twelve to twenty-four hours and then disappeared completely. Nystagmus was noted occasionally during the first few hours immediately after the intrathecal instillation. No sensory changes or persistent sphincteric disorders were observed. Appreciable amounts of streptomycin (4.5 to 17.0 micrograms per cubic centimeter) were always present in the cerebrospinal fluid forty-eight hours after the intrathecal administration of 0.2 to 0.375 Gm. of the drug (table 3). It is possible, therefore, that accumulation of the drug occurred after the repeated intrathecal injections.

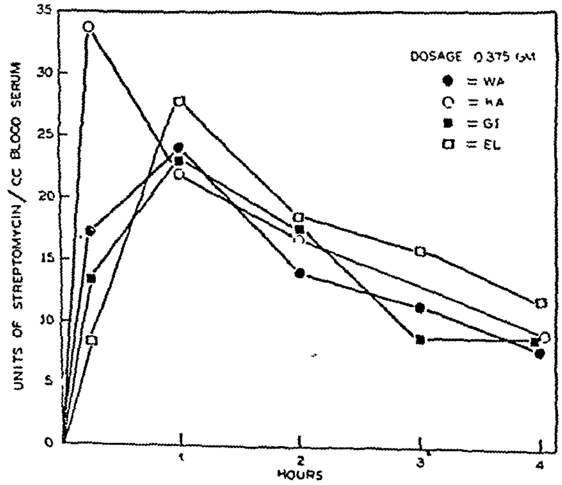

Chart 2.—Four hour absorption excretion tests, showing the concentration of streptomycin in the blood serum.

Manifestations of Anaphylaxis.—In 2 female subjects (Ro, Ra) definite evidences of anaphylaxis developed on the ninth day of therapy. The reactions were similar to those observed after the administration of a number of chemotherapeutic agents, for instance, oxophenarsene hydrochloride, sulfonamide drugs, thiouracil and organic gold preparations. In both women the sensitivity to streptomycin was characterized by: an itching maculopapular eruption over the trunk and extremities; increase in temperature; nausea and vomiting; the development of hypotension when administration of the drug was continued, and eosinophilia. The eruption became purpuric in the area distal to a tourniquet in 1 subject. However, the values for the bleeding and clotting times and for the total number of platelets were all within normal limits. Moreover, when the eruption was fading, application of the tourniquet was not followed by the appearance of purpura.

---

[13] Footnotes 1 and 2.

In both subjects the evidences of sensitivity to the drug subsided within one week. During the ensuing weeks the reaction was repeatedly reproduced in mild form by the intramuscular administration of single small (0.037 Gm.) doses of streptomycin. In 1 subject (Ra) it was possible to resume treatment without reaction five weeks after the original institution of therapy. The other subject (Ro) still exhibited evidences of sensitivity at the end of the fifth week but was able to tolerate the standard regimen twelve weeks after the institution of therapy.

* Average of 3 to 6 specimens. † Eighteen month old infant.

On the seventy-fourth day of the second course of therapy there developed in this patient (Ro) a moderately acute synovitis, which involved the proximal interphalangeal joints of the hands and feet. At the time of the appearance of the articular involvement an eosinophilia of over 30 per cent was present. The administration of streptomycin was continued for approximately six weeks after the onset of the synovitis. Despite the continuation of therapy, the clinical evidences of joint involvement steadily diminished but had not entirely disappeared three months after the initial symptoms.

Eosinophilia with Questionable or No Eruption.—Eosinophilia appeared in 14 of the 16 subjects at some time during the one hundred and twenty days of streptomycin therapy (chart 3). A percentage of eosinophilia of 5 or more, on at least two occasions, is designated eosinophilia. In 5 instances the eosinophilia first appeared between the ninth and the twenty-third days of therapy, and in 2 of the 5 subjects the onset of eosinophilia coincided with the appearance of a definite (Ro, Ra) or a questionable eruption. The eruption designated as "questionable" consisted of a minimal itching dermatitis which persisted for only twenty-four hours, and which was usually limited to a single area, such as an antecubital fossa, the anterior part of the chest or the face. In 2 patients a minimal conjunctivitis which persisted for one to two days appeared along with slight itching, but in both subjects the conjunctivitis disappeared spontaneously without any residuum. These phenomena were so mild and ephemeral that it was difficult to relate them with any degree of certainty to the administration of the streptomycin. The first appearance of eosinophilia in the other 9 subjects occurred during the second and the third months of therapy. In 1 patient the eosinophilia appeared on the seventy-fourth day of therapy, ten days after the cessation of the intrathecal administration of streptomycin. The eosinophilia varied from an intermittent phenomenon which was present for one or two weeks at a time to a constant finding which persisted for as long as sixty to a hundred days. In all the subjects the percentage of eosinophils fell gradually to below 5 within four to six weeks after the cessation of therapy.

The magnitude and the course of the eosinophilia in 11 subjects is presented in chart 3. In 7 patients the percentage of eosinophils increased to 10 or more and in 2 instances to 36 or above. Other than the 2 instances of characteristic drug rash and the occasional occurrence of transient pruritus, there were no symptoms associated with the presence of the eosinophilia save for the synovitis which appeared in the 1 subject (Ro). A transient leukopenia (3,000 to 4,000 cells per cubic millimeter) without granulocytopenia appeared in 2 persons at the time of the eosinophilia.

Effects on the Kidney.—Cylindruria appeared in 14 of the 17 subjects at some time during treatment with streptomycin. The onset of the phenomenon was striking in 10 persons, as it occurred within forty-eight hours of the institution of therapy. In the others the excretion of casts did not appear until after four to six weeks of treatment. Granular, hyaline and occasionally cellular casts were excreted. In 3 subjects the casts appeared only infrequently and in minimal numbers. In the other 11 patients, however, the cylindruria was essentially constant as long as the urine was highly acid. The centrifuged specimens of acid urine excreted by these persons usually contained 3 to 5 casts per low power field, and occasionally as many as 15 or 20. At the end of the fourth week of streptomycin therapy, the p_H of the urine of 7 subjects was maintained around 5.0 for a three day period by the oral administration of ammonium chloride. In all 7 subjects there was a sharp increase in the cylindruria, and in 4 instances on several occasions innumerable casts were excreted. When the urine was maintained at a neutral or slightly alkaline p_H (7.0 to 7.5) by the administration of sodium bicarbonate, cylindruria was demonstrable in only 1 subject. In general, throughout the period of the experiment, whenever the p_H of the urine would drop to 5.5 or below, cylindruria would reappear. During the fourth month of the study, the ammonium chloride regimen was reinstituted for a four-day period in 11 subjects of the experiment and in an additional 5 tuberculous patients who were not receiving streptomycin. There was no cylindruria in any of the latter group despite the acidification of the urine. In the streptomycin-treated subjects only minimal and sporadic cylindruria appeared during the three-day period after the cessation of adjuvant alkali therapy. Forty-eight hours after acidification, however, cylindruria appeared in 9 of the 11 subjects.

As the possibility existed that the cylindruria was a phenomenon unique to the particular preparation of streptomycin used, two preparations (streptomycin hydrochloride and streptomycin trihydrochloride calcium chloride complex[14]) of different manufacture were tested in a similar fashion. Cylindruria similar to that observed following the use of the highly purified sulfate was also noted after the administration of these other preparations of streptomycin.

No significant hematuria or albuminuria developed in 15 of the 16 subjects during the one hundred and twenty day period of treatment. Observations on the 1 patient who presented abnormal urinary findings are presented later in detail.

Renal Function.—In 14 of the 16 subjects the values obtained in the determinations of renal function (urea clearance, concentration and dilution and biweekly blood urea nitrogen) all remained within normal limits throughout the period of streptomycin therapy. In 1 person (St) the urea clearance progressively fell from a range of 85 to 100 per cent of normal to 50 to 60 per cent of normal. At no time was there an elevation of urea nitrogen or albuminuria, and this subject was one of the few who never exhibited cylindruria. One patient, however, (Ir, chart 4) manifested definite evidence of impairment of renal function coincidentally with the administration of the drug. This patient was a Negro woman aged 33 with an exudative tuberculosis of the lower lobe of the left lung, which presented the clinical signs of pneumonic consolidation. On entry to another hospital she was believed to have pneumococcic pneumonia, and sulfadiazine and penicillin were administered without obvious effect. The diagnosis of tuberculous pneumonia was subsequently established, and the patient was transferred to the New York Hospital. There was no history of symptoms suggestive of renal disease or previous hypertension, and the blood pressure in millimeters of mercury ranged between 90 and 118 systolic and 55 and 68 diastolic during the experimental period. Previous to the streptomycin therapy the patient had considerable fever, with a maximum daily temperature between 39 and 40 C. (102 and 104 F.). Neither the liver nor the spleen was palpable. The serum albumin ranged between 2.6 and 3.0 Gm. and the values for globulin were between 4.0 and 4.6 Gm., per hundred cubic centimeters. The total erythrocyte count was 3.9 million, with 9 Gm. of hemoglobin. On two occasions during the acute febrile illness, a 2 plus albuminuria without cylindruria occurred, but the other eight pretreatment specimens of urine were all normal. The blood urea nitrogen level was not elevated (10 mg. per hundred cubic centimeters). Immediately prior to therapy, the urea clearance was 97.5 per cent of the average normal value, the maximum specific gravity of the urine was 1.030 and the minimum specific gravity was 1.002. It was believed that the occasional albuminuria was related to the high fever, the hypoproteinemia was a reflection of the long-continued infection and the renal function of this subject was normal. In the light of subsequent events, it is possible that impaired renal function was present before therapy but was masked by increased renal blood flow consequent to the high fever.

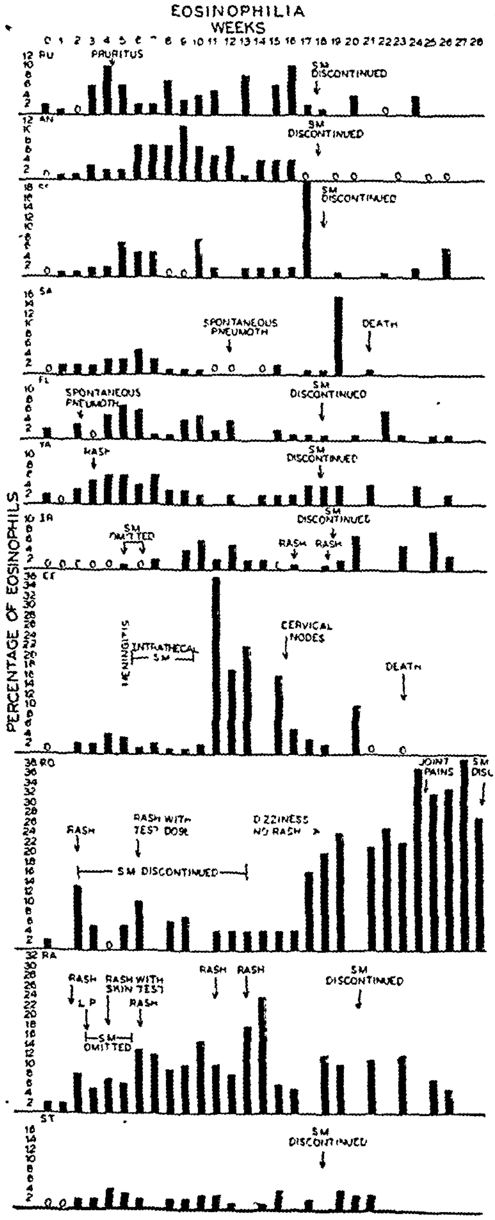

Chart 3.—Relationship of eosinophilia to streptomycin (*SM*) therapy.

Within twenty-four hours of the institution of the streptomycin therapy, albuminuria reappeared and was accompanied by the excretion of 15 to 20 casts per low power field of centrifuged specimens of urine (p_H 5.0 to 6.5). The albuminuria and cylindruria continued throughout the ensuing two month period, including a ten day interval during which streptomycin was not administered. In contrast to that of the other subjects, the cylindruria of this patient could not be eliminated by adjuvant alkali therapy, although the number of casts was considerably diminished when an alkaline urine was excreted.

---

[14] The material for this aspect of the investigation was kindly supplied by Merck & Co., Inc., Rahway, N. J.

As may be seen in chart 4, the values for the blood urea nitrogen remained within normal limits until the fourth week of therapy, when a rise to 20 mg. per hundred cubic centimeters occurred. At this time (day 30) treatment was interrupted for a ten day period, during which the blood urea nitrogen fell to normal levels. On reinstitution of streptomycin therapy, the blood urea nitrogen again rose within a week to a level of 24 mg. per hundred cubic centimeters. During the ensuing sixty days of therapy, the values for the blood urea nitrogen fluctuated between 16 and 24 mg. per hundred cubic centimeters. A decrease in renal function, as determined by the urea clearance, accompanied the nitrogen retention. At the end of the first two weeks of treatment the urea clearance had dropped to 62 per cent, and at the end of sixty days of therapy it had fallen to approximately 40 per cent. No impairment of the ablity to concentrate urine was ever demonstrable.

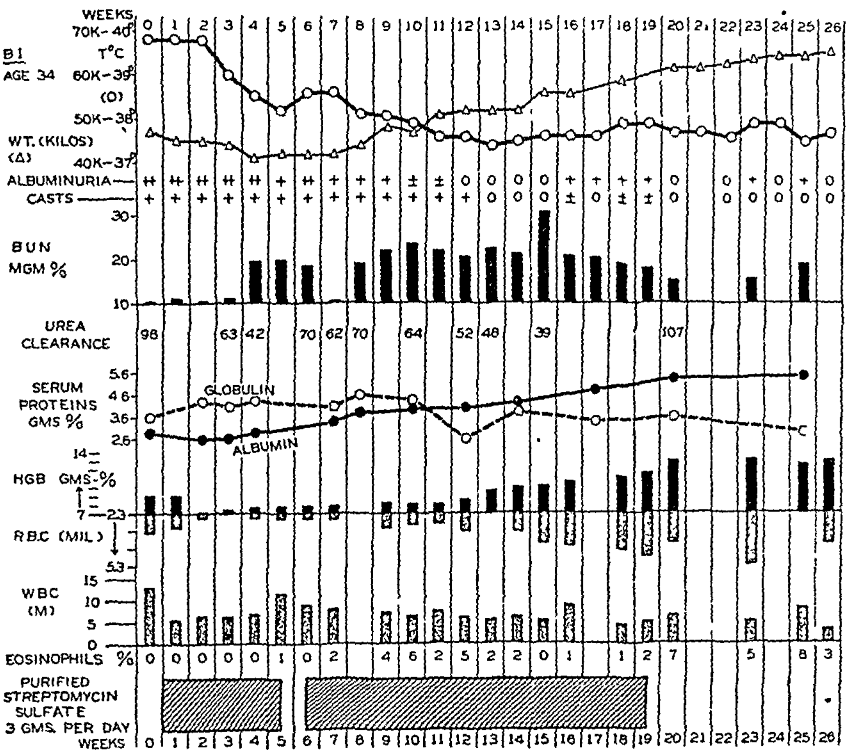

Chart 4.—Course of renal function in patient in whom reversible renal insufficiency developed during streptomycin therapy.

During the third month of observation, despite the continued administration of the streptomycin, the albuminuria decreased and the cylindruria was appreciably diminished. The values for the urea clearance and the elevation of the blood urea nitrogen remained essentially unchanged. Throughout the last thirty of the one hundred and twenty days of treatment, the urea nitrogen in the blood gradually fell to within normal limits, although minimal albuminuria and cylindruria persisted. Shortly after the cessation of treatment, the albuminuria and cylindruria ceased entirely, the value for the blood urea nitrogen was 10 mg. per hundred cubic centimeters and the urea clearance had assumed a normal value (102 per cent). The recovery was maintained during the six week period of subsequent observation. It is conceivably relevant that the arrest and subsequent reversal of the renal insufficiency of this patient occurred during the same period in which her tuberculous pneumonia resolved almost completely.

Histologic Examination.—Three subjects, Co, Sa and Te, had received the highly purified streptomycin sulfate for one hundred and fifty-four, one hundred and forty-two and ninety-three days, respectively, at the time of death. All these subjects had shown a considerable degree of cylindruria at various times during treatment. In all 3 instances gross and microscopic examination of the kidneys at postmortem examination disclosed no abnormalities which were attributable to the streptomycin therapy.

Neurologic Abnormalities. — Vestibular Function: Symptoms of vestibular dysfunction appeared between the seventeenth and the twenty-fifth days of therapy in all 16 subjects. This reaction is characterized by the appearance of a mild headache, which disappears within twenty-four hours and is followed by the development of symptoms which resemble vertigo. The sensations differ from vertigo in that they seem to occur in a linear rather than a circular plane. At the completion of a sudden movement, such as reaching for an object, sitting up or leaning to one side, the afflicted person feels as though the movement was continuing in the same direction in which it had been going. Thus he experiences the sensation either of past pointing or of falling in the direction of the previous movement. Occasionally, a momentary delay in focusing the eyes after a sudden change in position will be noted. At the height of the reaction 1 patient displayed striking pendulum movements, similar to those observed in labyrinthectomized animals. When he assumed the erect sitting position suddenly, he swayed back and forth rhythmically for approximately sixty seconds.

There was a considerable variation in the intensity of the vestibular dysfunction experienced by the different subjects. The reaction was negligible in 6, moderately severe in 8 and severe in 2 members of the group. In 2 subjects in whom the reaction was designated as negligible, the symptoms would occur only after unusually sudden movements; they were fleeting and were predominantly of the ocular variety. In the remainder of the group, however, the symptoms were incapacitating. At the peak of the reaction these subjects were unable to sit up in bed unassisted and with the slightest motion were acutely uncomfortable even when lying flat. They were frequently nauseated, and occasionally they vomited. The symptoms usually persisted in an acute form for seven to ten days and then subsided almost entirely. The disappearance of the acute symptoms occurred with striking rapidity, sometimes within a period of twenty-four hours. In no instance, however, did complete recovery occur with the subsidence of the acute symptoms. Instead, the subjects entered into a phase in which the symptom was absent during ordinary activity but could be evoked momentarily by an unusual stimulus, such as an abrupt shaking of the head. One subject (An) experienced a second attack of acute symptoms after a two week interval during which the sensations were latent. This person's initial attack of vestibular dysfunction was among the severest in the entire group. Although the second attack was of comparable severity, it disappeared within a period of three days.

In general the stage of latent vestibular dysfunction persisted for approximately sixty days and then disappeared. During the fourth month of therapy all subjects except 1 were completely free from these symptoms while reclining or sitting erect in bed. The exception was the man who had shown the "pendulum" movements. His symptoms also had virtually disappeared at the end of the one hundred and twenty day period of treatment. Four of the subjects, however, who were symptom-free while sitting erect in bed, had difficulty in maintaining balance when an ambulatory regimen was resumed. Ataxia was absent as long as these persons could orient themselves visually with any fixed object. A staggering gait was present, however, when they attempted to walk in the dark or with closed eyes. In these particular instances the symptom has not been disabling and has slowly diminished in intensity during the nine months since the cessation of therapy. In no instance was streptomycin therapy interrupted because of vestibular dysfunction.

A noteworthy feature of the reaction manifested by vestibular dysfunction is the fact that nystagmus was seldom encountered. Only 1 patient (Ph) manifested a sustained nystagmus, although in several other subjects fleeting nystagmoid movements of questionable significance were observed. In a patient not included in this series, treated subsequently with the same lots of streptomycin, a rotary nystagmus was observed.

With the particular technic used, it was not possible to demonstrate at the height of the reaction or subsequently an abnormal response to caloric stimulation of the vestibular apparatus in the majority of the group. In the remainder of the persons a definitely sluggish response to caloric stimulation was observed. It is probable that, by the use of more quantitative technics, it would be possible to demonstrate a hypofunction of the vestibular apparatus in most, if not all, persons who experience this reaction to streptomycin.

Cochlear Function: Deafness developed in 2 of the 16 subjects during the period of treatment. The loss of hearing was virtually complete in 1 person and amounted to more than 50 per cent of total hearing in the other. In both instances the deafness appeared after the repeated intrathecal administration of streptomycin for the treatment of tuberculous meningitis. Deafness, virtually complete in extent, has also developed in 3 of 15 patients treated subsequently with the same preparation of streptomycin, but who were not included in the present study. Two of these persons also had received repeated intrathecal instillations of streptomycin for tuberculous meningitis, and the third patient had decidedly impaired renal function. Thus, in a total group of 31 patients treated with the highly purified streptomycin, deafness appeared in 4 subsequent to intrathecal treatment for meningitis and in a fifth who had uremia.[14a]

It was not possible to observe the effect of the cessation of treatment with the drug on the deafness of the 2 patients of the present study because of a fatal outcome of the tuberculous meningitis in both instances. In the patient (Co) in whom a 50 per cent loss of total hearing developed during intrathecal administration, the subsequent administration of streptomycin by the intramuscular route for a ninety day period caused no increase in the deafness.

No tinnitus or impairment of hearing developed during or subsequent to the streptomycin treatment in any other of the 14 subjects. Moreover, in these same persons, repeated audiometric examinations failed to disclose any loss of auditory function in the zones beyond the limits of clinical detection.

Other than vestibular dysfunction or deafness, repeated neurologic examinations of the entire group revealed no abnormal findings during or subsequent to the one hundred and twenty day period of streptomycin therapy.

Miscellaneous Observations.—Anemia did not appear in any of the subjects after the institution of streptomycin treatment. In several persons anemia which was present before treatment disappeared with improvement in the status of the infection.

Leukopenia, without granulocytopenia, appeared in 2 subjects in conjunction with the appearance of a drug sensitivity reaction. In another subject (Ph) leukopenia (2,000 to 3,000 cells per cubic millimeter) developed during the second month of therapy. A relative granulocytopenia was also present. The administration of streptomycin was not interrupted. The leukopenia persisted for approximately sixty days but eventually disappeared. It is doubtful that this phenomenon represented a toxic reaction to the streptomycin. The subject, who is a radiologist, states that his total leukocyte count has "always been very low." Moreover, at the start of streptomycin treatment he was suffering from acute hematogenous tuberculosis.

Thrombocytopenia was never observed. Determinations of the bleeding, clotting and prothrombin times were made on several occasions, but normal values were always present.

There was no evidence that the administration of the streptomycin resulted in any damage to the liver. The values for the retention of sulfobromophthalein sodium were within normal limits before and throughout the experiment in 9 of the 16 subjects. In the remaining persons, all of whom had acute hematogenous tuberculosis, 16 to 36 per cent of the dye was retained (at forty-five minutes) in the test performed immediately before the institution of therapy. Subsequent observations when the acute infection had largely subsided revealed retention values which were within or close to the normal limits. In 11 of the series, the values for the thymol turbidity were within the normal range before and during the period of treatment. Values slightly higher than normal (5.8 to 10 units), observed in 5 subjects, fell to normal as the tuberculous infections improved. Variations in the amount of plasma protein and the respective amounts of albumin and globulin observed during therapy were no greater than could be attributed to the variations in the state of the tuberculous infection.

Visual acuity and the visual fields of all the subjects remained unimpaired during the one hundred and twenty day period of streptomycin therapy.

[14a] Examination of the brains of 4 of these subjects revealed liquefaction necrosis in the ventral cochlear nuclei. Similar changes were noted in the inferior vestibular nucleus in 1 of 2 brains which were studied. These observations are reported elsewhere (Stevenson, L. D.; Alvord, E. C., Jr., and Correll, J.: Proc. Soc. Exper. Biol. & Med., to be published).

COMMENT

From the foregoing observations it is evident that 0.375 Gm. of highly purified streptomycin sulfate administered at three hour intervals for one hundred and twenty days is remarkably well tolerated by tuberculous persons. It is also evident, however, that all the manifestations of toxicity which may occur from the use of impure streptomycin (histamine reaction excepted), have been observed after the administration of the highly purified streptomycin sulfate. The question immediately arises as to whether the observed instances of toxicity were produced by streptomycin per se, by residual impurities in the highly purified material or by a change in the nature of the compound which conceivably might occur during its conversion to the salt. It is unlikely that the sulfate itself is responsible, for identical toxic manifestations have occurred after the use of streptomycin hydrochloride. Moreover, the total daily dose of sulfate (0.6 Gm.) is well within the limits of the tolerated dosage of this substance.

Although the streptomycin used in the present investigation was prepared from crystalline material, it does not necessarily follow that the material was entirely pure. Craig and his fellow workers[15] have amply demonstrated by means of the counter-current differential phase method of extraction that such substances as synthetic antimalarial compounds and crystalline penicillins are by no means single chemical entities. The antibacterial potency of the streptomycin used in the present study coincided with the theoretic potency for pure material. The acute toxicity observed on the intravenous injection of the material to mice (table 1) was not so low as has been occasionally observed from the use of considerably less pure material. However, it has not been established that a correlation exists between the degree of purity of a preparation of streptomycin and its acute toxicity on intravenous administration to mice.[16]

On the basis of the manufacturer's examinations, in which the currently available biologic and chemical technic were employed, it has been determined that the four lots of streptomycin used in the present investigation were all at least 95 per cent pure (table 1). Thus, in the interpretation of the toxic reactions observed in the present investigation, the significance of the less than 5 per cent of adventitious substances present in the streptomycin must receive consideration. It should also be emphasized that the clinical significance of the various manifestations of toxicity can be evaluated at this time only on the basis of a four to eight month period of observation. The possibility exists that toxic reactions now regarded as minor might assume greater importance on long-continued observation.

There are innumerable chemical compounds which on occasion will give rise to manifestations of anaphylaxis on administration to human subjects. Thus, either the antibacterial substance or impurities might have been responsible for the reactions of sensitivity to the drug which were observed in some persons in the present study.

The moderately severe sensitivity reactions which appeared in 2 subjects were clinically similar to those which have been observed after the administration of organic arsenicals, sulfonamide compounds, salts of gold, penicillin, thiouracil and other chemotherapeutic agents. With the streptomycin reactions, as with the similar reactions to other agents (notably arsenic), the duration of clinically detectable sensitivity was self limited. In both subjects it was eventually possible to renew the administration of streptomycin without producing sensitivity phenomena other than the eosinophilia. It is conceivable that, if streptomycin therapy had been continued despite the appearance of the reactions, the ultimate outcome would have been the same. However, from experience with the similar reactions to other agents, it is not unlikely that in some patients, perhaps one half, the continuation of therapy in such circumstances will be followed by more serious anaphylactic phenomena. Therefore, unless the indications for streptomycin therapy are urgent, it seems advisable in the presence of such reactions to interrupt therapy for three to eight weeks or until the period of clinically demonstrable sensitivity to the drug has passed.

The appearance of eosinophilia in 14 of the subjects is a disquieting phenomenon, in view of the work of Rich and others,[17] on the possible association of sensitivity to the drug with the development of diffuse vascular disease. During the period of observation, however, there was only 1 instance of synovitis and none of arthritis, myositis or other symptoms suggestive of diffuse vascular disease. The possibility that the eosinophilia was related to the effect of the drug on the tuberculous infection can neither be affirmed nor denied.

It is probable that the development of cylindruria without other evidences of renal disease is not in itself a reaction of serious clinical significance. This would be particularly the case if it could be demonstrated that the concomitant administration of alkali actually prevents, rather than masks, the phenomenon. The cylindruria presumably results from damage to the epithelium of the proximal convoluted tubules. The reason for this assumption is the fact that these structures were extensively involved in a fatal nephrosis which was presumably attributable to therapy with impure streptomycin.[4] Moreover, in unpublished observations in this laboratory, 1 of 3 dogs which received large doses of impure streptomycin sulfate died in uremia and showed damage to the proximal convoluted tubules on postmortem examination. It should be emphasized, however, that in the lesion produced in the dog glomerular changes were prominent and the tubular lesions were minimal.[4]

If the cylindruria observed in the present investigation arose from the proximal convoluted tubules, it is conceivable that alkalinization of the urine did not prevent the phenomenon but merely facilitated the solution of the casts. If the sole effect of alkalinization were to dissolve casts already formed, however, it would not be anticipated that a change in the p_H of the urine from 6.0 to 5.0 would result in such an increase in cylindruria as was observed in the present study. It should be possible to establish the precise effect of alkalinization on the cylindruria which accompanies streptomycin therapy by suitable experiments in dogs.

The nitrogen retention and reduced renal function which appeared in 1 subject presumably represents a more advanced form of the same process which was characterized only by cylindruria in the other patients. It is possible that this subject had undetectable renal damage prior to therapy. Albuminuria and cylindruria appeared immediately after the institution of streptomycin, the blood urea nitrogen rose, and the urea clearance fell within the ensuing three weeks. Moreover, during the ten day interval (day 30 to day 40) in which no drug was administered, the blood urea nitrogen returned to a normal level although the urinary abnormalities and the reduced urea clearance remained unchanged. During the second two months of therapy, however, in association with a pronounced improvement in the subject's tuberculous infection, the albuminuria and cylindruria virtually disappeared. The results of urinalyses and renal function tests did not become entirely normal until the streptomycin therapy had been discontinued.

[17] Rich, A. R.: Role of Hypersensitiv[illegible] Periarteritis Nodosa as Indicated by Seven Cases Developing Du[illegible] d Sulfonamide Therapy, Bull. Johns Hopkins H[illegible] 1942. Longcope, W. T.: Serum Sickness an[illegible] from Certain Drugs Particularly Sulfonamides, [illegible] (Sept.) 1943.

Thus, whether the observed evidences of renal damage resulted solely from the drug or represented an effect of the drug on diseased kidneys, it appears that the process was arrested and definite improvement occurred despite the continued administration of streptomycin.

It is probable that the observed effect on the kidney is produced by streptomycin itself and not by an accompanying impurity. If the latter were responsible, it would be necessary to postulate the existence of an unusually nephrotoxic substance. On the regimen used, the total daily dose of "impurities" must have been small, and yet the cylindruria frequently appeared within seventy-two hours of the institution of therapy.

It also appears that the neurologic reaction was produced by the drug and not by associated impurities. Although the degree of vestibular dysfunction observed in the present study was seldom severe, it has not been possible to establish unequivocally that the reaction was uniformly less severe than that produced by streptomycin containing 30 to 50 per cent "impurities."[3] The possibility exists, however, that the highly purified material is less neurotoxic than impure material, and it may subsequently be possible to affirm or deny this hypothesis.

The mechanism by which the vestibular dysfunction is produced is not established. Presumably the site of this action of the drug is centrally situated, as the loss of labyrinthine function is bilaterally symmetric.[18] The reaction may be an intoxication which is reversible up to a point but which results in more persistent damage if the administration of streptomycin is continued. The ataxia produced in dogs by the administration of large doses of impure streptomycin (0.180 Gm. per kilogram of body weight daily) was notably severer in the evening after the last daily dose than in the morning when no drug had been administered for twelve hours.[4] Moreover, in human beings the interval between the institution of streptomycin therapy and the time of the onset of symptoms of vestibular dysfunction appears to be directly related to dosage. On the 3.0 Gm. a day regimen used in the present study the reaction appeared on approximately the twenty-first day. With larger daily doses the reaction has been observed at an appreciably earlier period, and with smaller doses (1 to 2 Gm. a day) it usually has been delayed until approximately the twenty-eighth day of treatment.[18] Although precise observations are not yet available, it appears that the reaction does not become evident at all if a daily dose of 3 Gm. or less is administered for only a short period.

The disappearance of all symptoms of vestibular dysfunction despite the continued administration of streptomycin presumably reflects the activation of compensatory mechanisms rather than the restoration of vestibular function.[18] The duration of the period of depressed vestibular function is not established, but it is possible that the condition may be permanent. In the present investigation complete symptomatic recovery occurred in all subjects. However, if symptomatic recovery is dependent on compensatory mechanisms it is conceivable that the degree of recovery might not always be complete. On the basis of an extensive experience with the clinically available streptomycin, Brown and Hinshaw[3] have suggested that symptomatic recovery may be appreciably less complete in elderly persons.

The fact that, among 31 patients treated with highly purified streptomycin, deafness occurred only after intrathecal administration of the drug or in the presence of well defined renal insufficiency suggests that this reaction may be the result of overdosage. Support for this opinion is afforded by the study of Brown and Hinshaw, in which deafness was observed only after intrathecal administration of streptomycin or in patients who had received a daily dose of 5 to 10 Gm. of the drug by the intramuscular route. In both the Mayo Clinic study and the present investigation the majority of the persons in whom deafness developed during streptomycin therapy were patients with tuberculous meningitis. It is possible that in many instances the meningitis rather than the drug therapy was responsible for the production of the deafness. However, 1 of the subjects of the present investigation in whom total deafness developed had acute hematogenous tuberculosis without any evidence of involvement of the central nervous system.

It is evident that highly purified streptomycin is a chemotherapeutic agent of low toxicity, since it was possible to administer moderately large doses of the drug for such a long period to persons who were seriously ill. It is also evident that the drug is by no means innocuous, for it produces eosinophilia and the symptoms of vestibular dysfunction with uniformity, and, in large doses, may produce deafness.

An evaluation of the toxicity of a chemotherapeutic agent cannot be made with precision without consideration of the particular diseases against which the drug is to be employed. It would seem that the long-continued administration of streptomycin will be employed principally in the treatment of tuberculosis and, less frequently, in acute brucellosis and certain instances of bacterial endocarditis. On the basis of the present investigation it appears that the toxicity of highly purified streptomycin is sufficiently low to justify its long-continued administration to patients with actively progressing tuberculosis and other comparably serious infections. Conversely, it appears that streptomycin should not be employed in the treatment of relatively benign infections, such as recently developed minimal tuberculosis or chronic brucellosis, until the question of possible late effects resulting from the use of the drug can be determined.

SUMMARY

1. An investigation of the toxicity of streptomycin was made in a group of tuberculous subjects, who received 3 Gm. of highly purified streptomycin sulfate daily for one hundred and twenty days.

---

[18] Fowler, E. P., Jr., and Seligman, E.: Otic Complications of Streptomycin Therapy, J. A. M. A. 133: 87-91 (Jan 11) 1947.

2. It was necessary to interrupt therapy in only 2 patients. In both instances the reactions to the drug were anaphylactic in character, and it was possible to resume treatment eventually in both subjects.

3. The highly purified streptomycin caused appreciably less irritation at the site of intramuscular injection than did the drug available for general clinical use.

4. The repeated intrathecal administration of 0.1 Gm. of streptomycin was well tolerated. Larger amounts (0.2 to 0.375 Gm.) were well tolerated in some instances but at times produced untoward reactions of a potentially serious nature.

5. Except for the so-called histamine reaction, instances of all of the previously described manifestations of toxicity to streptomycin were observed after the use of the highly purified material. In addition, an intermittent or sustained eosinophilia ranging between 5 and 39 per cent was noted in 14 of 16 subjects.

6. Symptoms of vestibular dysfunction of variable severity appeared uniformly on approximately the twenty-first day of therapy. Complete symptomatic recovery eventually occurred in all subjects. The recovery was presumably a result of the activation of compensatory mechanisms rather than of the restoration of labyrinthine function. It is not possible to establish at this time whether the neurologic reaction observed in this study was less severe than the reactions which have occurred after the use of impure material.

7. Deafness developed in 2 of the 16 subjects in the study and in 3 persons treated subsequently with the same preparation of streptomycin. Four of the instances of deafness occurred after the intrathecal administration of the streptomycin, and the fifth developed in a subject with pronounced renal insufficiency.

8. Cylindruria appeared intermittently in the majority of the subjects, and it was present uniformly when a highly acid urine was excreted. Reduction in renal function appeared in only 2 persons, and in 1 of these the restoration of normal function occurred despite the continued administration of the drug.

CONCLUSIONS

The immediate toxicity of highly purified streptomycin sulfate on long-continued administration is sufficiently low to justify the use of the drug in the treatment of serious protracted infections, such as most forms of tuberculosis. As streptomycin can produce potentially serious toxic reactions, however, it is inadvisable to use the drug in the treatment of generally benign infections, such as recently acquired pulmonary tuberculosis of minimal extent.

Vaccinia.—The virus of vaccinia, although not yet obtained in crystalline form, has been obtained in a state of great purity (McFarlane and others, 1938, 1939; Smadel and Hoagland, 1942). Like the bacteria and the mosaic viruses, the vaccinia virus is composed at least in part of nucleoprotein. In addition, it contains carbohydrate and fat. There is also evidence of the presence of complex enzyme systems (flavine, adenine, dinucleotide, biotin and copper), some of which at any rate are related to respiratory activity of living cells. McFarlane et al. (1939) suggest that the vaccinia virus particles have a loose outer shell of lipoid, a structural arrangement analogous to bacteria.—Van Den Ende, M.: Laboratory Aspects of Some Recent Advances in Medicine, *South African M. J.*, April 26, 1947.

VITAMIN D ("ERTRON") THERAPY IN ARTHRITIS

Treatment Followed by Massive, Metastatic Calcification, Renal Damage and Death

PAUL KAUFMAN, M.D.
R. DONALD BECK, M.D.
and
RICHARD D. WISEMAN, M.D.
New York

Several instances of high potency vitamin D ("ertron") intoxication have been published lately in the medical literature; all patients recovered except 1 infant, who died and whose postmortem findings showed calcification in the renal tubules.[1] To our knowledge the case which we report is the first in which death followed the long-continued use of this preparation by an adult and in which autopsy confirmed the diagnosis of vitamin D intoxication. The case is reported because it further proves the danger of high doses of vitamin D and of the regrettable practice of noncontrolled self medication with some of the vitamins, and because it disproves the unwarranted claim of harmlessness made by some of the manufacturers of high potency vitamin D preparations.

REPORT OF A CASE

First Admission.—A woman aged 63 was admitted to Goldwater Memorial Hospital Dec. 28, 1942. She was badly crippled by a rheumatoid arthritis of thirteen years' duration. In the two years prior to her admission to the hospital she received one hundred injections of a gold preparation with temporary improvement.

Signs of deforming arthritis were found in several joints, predominantly in knees, elbows, wrists and fingers. Roentgenograms of these joints showed a moderately advanced rheumatoid arthritis without any suggestion of calcinosis. Laboratory data, including complete blood count, urinalysis and blood chemistry tests were essentially normal, except for a moderate secondary infectious type of anemia and a trace of albumin in the urine. During her stay at the hospital the patient received routine physiotherapy for the joints involved and afterward roentgen irradiation, which, however, had to be stopped after she became ill with anemia and diarrhea. In July 1943 the patient left the hospital in a somewhat improved condition.

Second Admission.—On July 4, 1945 the patient was readmitted and gave the history that after she left the hospital she went to Arizona for a change of climate. While there, on the advice of her private physician, she started to take daily 150,000 to 200,000 units of vitamin D as "Ertron" capsules (50,000 U. S. P. units each). This she continued for about fourteen months without any improvement. After spending eighteen months in Arizona the patient, on her way to the

East, consulted a physician in Chicago. He found pronounced symptoms of anorexia and vomiting. He had a series of gastrointestinal roentgenograms taken, with negative results. The patient continued to take the high potency vitamin D preparation after returning to New York until March 1945, when on the advice of another physician she discontinued it. At this time a draining abscess developed on the heel of the patient's right foot, and there was tenderness of the gums and teeth.

Roentgen examination of her teeth revealed many small apical abscesses, and all her teeth were extracted. During the next few months her foot continued to drain, and she then noticed similar areas on the other foot and on the backs of her hands. About three weeks before her second admission her left knee became uniformly swollen. During the last six months she had been extremely weak and had lost about 40 pounds (18 Kg.) because of decided loss of appetite, continuous nausea and frequent spells of vomiting. The patient had complained of severe headaches at the back of her head. She had generalized pruritus for five months without eruptions. She also had a cough productive of brownish sputum. Repeated attacks of frequency and burning on urination also were noted. There was no apparent fever but the patient had occasional chilly sensations.

Physical Examination.—On admission examination showed an emaciated, severely crippled, chronically ill, middle-aged woman, hardly able to move. The skin showed numerous scratch marks but no eruption. There was a tender mass about the size of a walnut, not freely movable, over the anterior portion of the right sternomastoid muscle. A lymph node the size of a pecan was found in the right axilla, and there were several smaller nodes in both inguinal and femoral areas. None of the nodes was tender, all were discrete and freely movable. The extremities showed appreciable wasting with severe articular deformities of the hands, feet, wrists, elbows and knees; all were extremely painful on motion. The fingers were spindle-shaped, the skin shiny. There was a draining abscess in the right heel with a punched out ulceration. Distinct multiple swellings were seen on the backs of the hands and on the dorsal aspect of the left foot. These swellings varied in size from a pea to a walnut, were extremely tender and had a doughy consistency. The left knee showed an exceedingly large uniform swelling. Examination of the lungs revealed essentially normal conditions except for a few moist rales in the left axilla. The heart was normal. The liver and spleen were not palpable. (Aspiration material from the knee is shown on figure 1.)

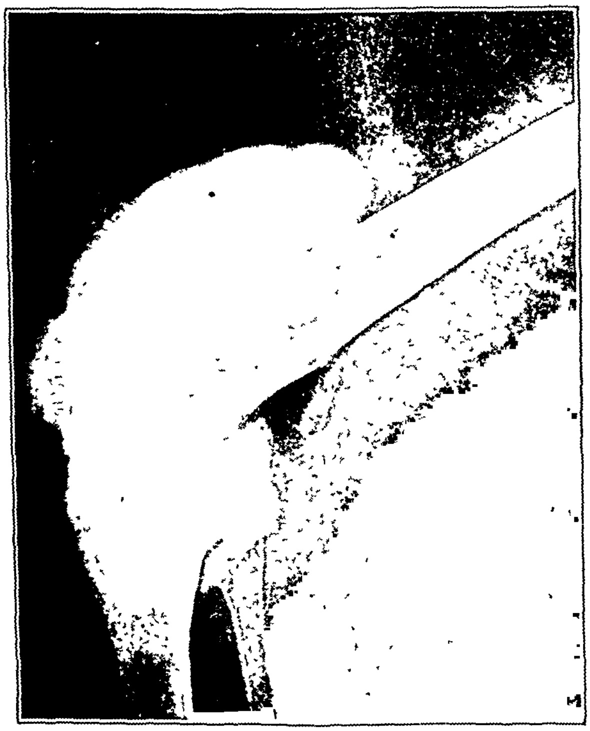

Fig. 2.—Left knee showing massive heterotopic (metastatic) calcification on Aug. 22, 1945. Calcium fills out completely the articular bursae. There are also calcific deposits in the soft tissue adjacent to the articular space. The popliteal artery shows calcification (lateral view).

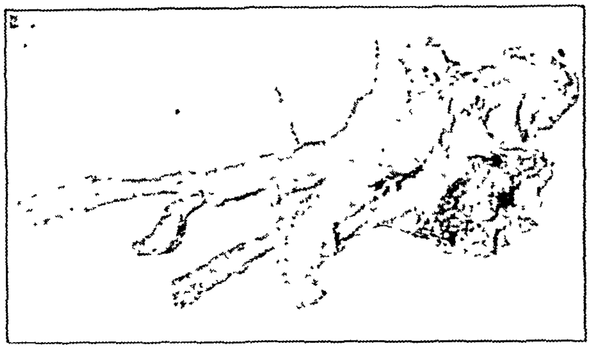

Fig. 5.—Black and white photograph of a "kodachrome" picture taken at autopsy and showing calcinosis of the renal artery.

Laboratory Data.—Examination of the blood on admission was as follows: Red blood cells 2,500,000; hemoglobin 6 Gm., white blood cells 7,800, with a differential count of 77 per cent polymorphonuclears, 12 per cent lymphocytes, 4 per cent monocytes and 1 per cent eosinophils. The urine was clear, yellow and alkaline, with specific gravity 1.012, albumin 2 plus, sugar 1 plus, and occasional epithelial cells in the sediment. The Wassermann test was negative; the level of nonprotein nitrogen was 96 mg., blood urea nitrogen 58 mg. and fasting blood sugar 100 mg. per hundred cubic centimeters. On admission the blood pressure was 125 systolic and 85 diastolic, the pulse rate 96, the respiratory rate 18 and the temperature 99 F.

Course.—Three days after admission the patient became acutely ill and vomited several times but remained afebrile. At this time Staphylococcus aureus was reported in the culture from the draining abscess on the right heel. Incision and drainage of the multiple abscesses was performed, and a biopsy of the lymph node was made. All these showed that the abscesses were not real abscesses and that they and the excised lymph node contained whitish yellow gritty material, which under microscope proved to consist almost entirely of calcium. Biopsy of one of the masses on the back of the left hand showed chronic, nonspecific, productive inflammatory reaction with calcinosis.

Penicillin therapy was started at this time because of the presence of Staphylococcus aureus in the culture.

Most of the roentgenograms of the joints revealed massive deposits of calcium around the articulations, especially in the left knee, where the calcium completely filled the articular bursae, and in the left ankle (figs. 2, 3 and 4).

On August 18 the nonprotein nitrogen was 129 mg. per hundred cubic centimeters, and the patient appeared to be failing rapidly. She was given large amounts of parenteral fluid together with oral ammonium chloride and ammonium mandelate in an attempt to acidify and increase the urinary output. A spinal tap done two days before her death was nonrevealing. The patient refused to eat, became weaker and died in uremia on Sept. 8, 1945.

Subsequent Laboratory Data.—Laboratory examinations following admission showed rapidly rising nonprotein nitrogen levels of 129, 133 and 153 mg. per hundred cubic centimeters, and six hours before her death there was a urea nitrogen determination of 107 mg. and nonprotein nitrogen of 172 mg. per hundred cubic centimeters. The carbon dioxide combining power stayed within normal limits, being 68 per cent and 46 per cent until the day of death, when it dropped to 35 per cent. The total protein was 6.6 mg. per hundred cubic centimeters, with an albumin/globulin ratio of 4.9/1.7. The blood calcium determination on Aug. 31, 1945 was 147 mg. per hundred cubic centimeters, phosphorus 6 mg. per hundred cubic centimeters and alkaline phosphatase 9.6 Bodansky units. The calcium level was 130 mg. per hundred cubic centimeters when the test was repeated one week later just before the death of the patient. Urinalysis continued to show an alkaline urine with a low specific gravity, a persistent albuminuria of 1 to 2 plus and an essentially clean sediment on microscopic examination, except for the large amounts of calcium phosphate crystals.

Final Anatomic Diagnosis.—The final diagnosis was calcinosis involving the joints of the extremities, the sternoclavicular joints, the costosternal articulations, subcutaneous tissue, the myocardium, the lungs, pancreas, parathyroid glands and the iliac and renal arteries. Apart from the calcinosis, the salient points of the gross pathologic diagnosis were: chronic rheumatoid arthritis, rheumatoid valvulitis of the mitral valve, chronic pericarditis with calcium deposits, aspiration lobular pneumonia and pyelonephritis. (The calcification of the renal artery is illustrated in figure 5.)

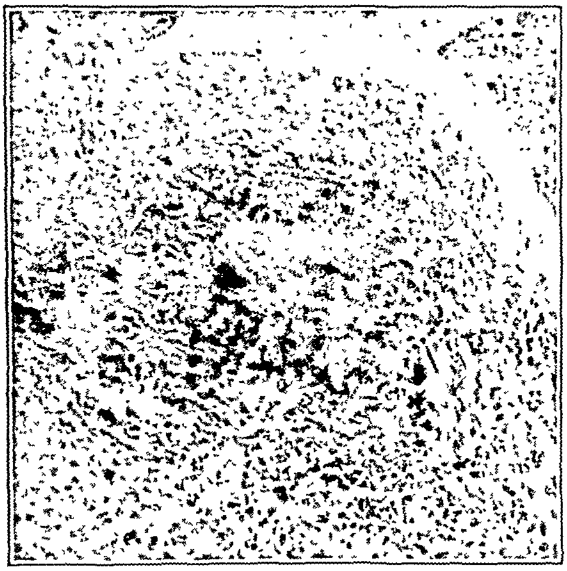

Fig. 6.—Masses of calcified tissue in the myocardium of the left auricle of the heart.

ABSTRACT OF MICROSCOPIC DESCRIPTION

Heart.—In the heart there were large, poorly circumscribed granulomatous lesions replacing the muscle fibers. These were made up of hyalinized connective tissue which was partially calcified, fragmented edematous collagen fibers, fibrocytes and pyknotic nuclear fragments. About some of the calcified areas were bizarre giant cells which appeared to be of the foreign body type. There were also a few Anitschkow myocytes and lymphocytes. These plaques were poorly vascularized, but in the surrounding myocardium there were many dilatated capillaries.

The epicardium of the left ventricle presented a bizarre picture. Over the surface were fragments of an exudate which was fibrinoid and also in a few places appeared partially calcified. There were rows of fibroblasts arranged at right angles to the surface. Elastic tissue stains of the left auricle showed fragmentation and proliferation in the region of the calcified lesions. (Figure 6 shows calcification in the myocardium.)

Lungs.—The alveolar septums of the lungs were greatly thickened by fibrous tissue, and within this were spicules of calcium and giant cells, some of which resembled those cells in giant cell tumors of bone; others were definitely of a foreign body type. There were a number of recognizable bronchi present which were dilatated, and the epithelium of these was partly calcified (fig. 7).

In the midst of solid sheets of fibrous tissue were small areas of granulation tissue and fragmented polymorphonuclear cells similar to those seen in the myocardium.

Renal Artery.—Sections of the renal artery showed large amounts of intimal sclerosis with splitting and reduplication of the internal elastica. There were flecks of calcium throughout the intima.

Parathyroid.—In one of the parathyroid glands there was a small colloid cyst lined by a single layer of flat epithelium. The overall size of the gland was not increased by this. The cell types were not unusual. The other gland was fragmented due to the presence of large amounts of calcium. Other cells were large and multinucleated and placed in the midst of proliferating fibrous tissue (fig. 8).

Kidneys.—Calcium deposits were found in the glomerular capsules. Some of the tubules of the kidneys (fig. 9) also showed calcification.

COMMENT AND SUMMARY

The history, the physical, laboratory, roentgen and pathologic data of this case furnish fairly conclusive evidence that this patient suffered and died of high potency vitamin D, "ertron" intoxication. There were no signs of calcinosis or renal insufficiency at her first stay at the hospital in 1942-1943. At the second admission she had massive calcinosis, extensive renal damage as evidenced by biopsy material, by pronounced hypercalcinemia and azotemia and by roentgen pictures of the affected joints. She died of uremia, and the gross pathologic observations showed massive calcification in and around several joints of the synovial membranes, soft tissues, lymph glands and the renal and iliac arteries.

On microscopic examination extensive deposits of calcium were found in the myocardium, lungs, parathyroid glands and pancreas, in the tubules and glomeruli of the kidneys and in the bronchial epithelium. The only event which occurred between the first and second admissions to which these changes can be attributed was the huge amount of "ertron" (150,000 to 200,000 units daily for about fourteen months) which the patient took for her rheumatoid arthritis.

As to the mode of action of high potency vitamin D intoxication, the experimental data and the evidence presented by this and other cases of vitamin D intoxication seem to indicate that tissue damage sometimes precedes, at other times follows, hypercalcemia. Apparently a vicious circle is created by the vitamin D, in which the higher the blood calcium level (or the greater its fluctuation, according to Ham and Portuondo[9]) the more extensive is the resultant calcification of tissue. On the other hand the more extensive the damage to the kidneys through the calcinosis, the less capable they are of excreting the concentrated calcium from the body fluids; further precipitation of calcium and further damage to the kidneys result.

At least that was the chain of events which occurred in the case reported here.

PULMONARY CALCIFICATION IN RELATION TO SENSITIVITY TO HISTOPLASMIN

HENRY B. ZWERLING, M.D.
Berkeley, Calif.
and
CARROLL E. PALMER, M.D.
Senior Surgeon, U. S. Public Health Service

It has recently been suggested that in the central eastern region of the United States there is a disease or a group of diseases which closely simulates tuberculosis. This has been indicated by the observation of pulmonary calcification in persons who are negative reactors to tuberculin but in whom the reaction to histoplasmin is positive. Until the past decade pulmonary calcification in the presence of a negative reaction to tuberculin has been considered a manifestation of a disturbance of the allergic mechanism, but the more probable explanation is that there is another disease or group of diseases which account for many instances of pulmonary calcification. That this is a likely possibility is demonstrated by the striking similarity in some instances of coccidioidomycosis to tuberculosis during the active and the end stages of disease.

Christie and Peterson[1] and Palmer[2] have shown a correlation of sensitivity to histoplasmin with pulmonary calcification in tuberculin-negative persons. Emmons[3] and Smith[4] have indicated that sensitivity to histoplasmin may not be specific. Whether the antigen is specific for present or past histoplasmosis is of secondary concern at the moment; of primary importance is the suggestive evidence of a disease which simulates tuberculosis and is apparently benign in many of its aspects. If histoplasmosis were to be considered the major cause of tuberculin-negative pulmonary calcification in the central eastern region of this country, it is evident that histoplasmosis is not necessarily a fatal disease, as had previously been considered.

A survey of student nurses in ten cities throughout this country has demonstrated a close parallel of sensitivity to histoplasmin with pulmonary calcification. In those cities in which pulmonary calcification is seen frequently the number of reactors to histoplasmin is high, and in those cities in which pulmonary calcification appears relatively infrequently the number of reactors is low. There is seen no significant parallel with the reaction to tuberculin. Since many of the student nurses lived for appreciable periods of time in cities other than those in which they train an attempt was made to map those places in which they had spent the major portion of their lives (Palmer[5]). Aside from significant interstate differences in sensitivity to histoplasmin, a definite intrastate variation was shown.

Recent data accumulated from Kansas City, Mo., by Furcolow[6] and his associates suggest that there are only slight differences in sensitivity to histoplasmin by sex and race. The lack of a higher incidence of sensitivity to histoplasmin in the Negro population is noteworthy in view of the known higher incidence of tuberculosis and positive reactions to tuberculin in this group.

ROENTGENOGRAPHIC OBSERVATIONS

To prove the existence of another disease which simulates tuberculosis roentgenologically, it would be necessary to obtain bacteriologic proof in instances of active pulmonary disease and then to follow these cases to an end stage of progressive disease or of healing with or without calcific deposition. A limited number of cases of this type have been studied in Kansas City, Mo., in which the roentgenogram of the chest demonstrated a parenchymal lesion with or without visible enlargement of the mediastinal lymph nodes; in these instances the reaction to tuberculin was negative and that to histoplasmin positive. Mycobacterium tuberculosis was not recovered. Further investigations are being conducted and will be reported on in the future.

With the present lack of bacteriologic proof it is possible to accept tentatively cutaneous testing as a method of directing one's thoughts and efforts toward the solution of this problem. In this respect there has been 1 instance of active disseminated pulmonary disease in a child, discovered in a school survey in February 1945. The skin tests, positive to histoplasmin and negative to tuberculin then, have remained so to the present. Definite evidence of beginning calcific deposition in these lesions was noted in January 1946.

Additional case material has been collected, in which the disease has not as yet progressed to the stage of calcification; in these there has been a small pulmonary lesion frequently associated with demonstrable enlargement of the lymph nodes. Under ordinary circumstances the lesion would be considered reinfection in minimal tuberculosis or a primary complex.

In 3 instances minimal lesions similar to those seen in pulmonary tuberculosis have appeared in persons who were previously negative to tuberculin and histoplasmin, and in whom roentgenograms of the chest had been negative. Within three months after negative cutaneous reactions and roentgenograms, the reaction to histoplasmin became positive and the lesion appeared. Recent follow-up films have indicated a persistence of the lesions for several months, suggesting a tendency to chronicity.

The impetus to the study of these instances of active disease resulted from the discovery of the correlation of tuberculin-negative pulmonary calcification with positive skin tests to histoplasmin. A distinction by roentgenography between tuberculin-positive, histoplasmin-negative calcification and tuberculin-negative, histoplasmin-positive calcification cannot be definitely made at this time. The calcified primary complex, massive hilar calcification and other types may fall in either group. However, disseminated bilateral calcification is more frequently associated with a positive reaction to histoplasmin than with one to tuberculin. High[7] has studied more than 100 instances of this type, including miliary calcinosis, of which approximately 90 per cent were positive to histoplasmin. Among these instances of disseminated calcification, 12 occurred in six pairs of siblings.

SUMMARY

It is probable that a disease other than tuberculosis and coccidioidomycosis accounts for a considerable number of instances of pulmonary calcification in the United

States. This disease or group of diseases apparently causes sensitivity to histoplasmin. By means of testing with histoplasmin, instances of active pulmonary disease have been discovered in school children in Kansas City, Mo., and in student nurses throughout the country which simulate pulmonary tuberculosis by roentgen examination.

ABSTRACT OF DISCUSSION

Dr. Charles E. Smith, San Francisco: While their approaches and the groups studied have been decidedly different, the results of Christie and Peterson of Vanderbilt and of Palmer and Zwerling of the Tuberculosis Control Division of the U. S. Public Health Service have checked closely. As Dr. Zwerling indicated today, neither group has committed itself to the etiology of the sensitivity to histoplasmin which so convincingly parallels pulmonary calcifications. This conservatism is appropriate, particularly in view of the questions which Emmons has raised regarding possible cross reactions. However, to one safely out of the area, it would appear that the noose is tightening around Histoplasma capsulatum. We are sure that such infections are not acquired in nature in California or other western states. Palmer's reported sensitivity to histoplasmin in California is recognized by him as the result of cross reactions in persons with coccidioidal infections. I am not qualified to discuss the roentgenologic aspects of these pulmonary lesions. A general pattern appears on the way so that statistically one could differentiate tuberculous infection. However, judging from our own experience with coccidioidal infections, exceptions appear with disconcerting frequency. One hopes that in the flush of histoplasmin enthusiasm we may exhibit Dr. Zwerling's caution in our conclusions with respect to our individual patients. Although a patient has histoplasmin (or coccidioidin) sensitivity, a pulmonary lesion may be tuberculous. Tuberculin testing and sputum and gastric cultures, smears and animal inoculations are as important as ever. An additional precaution should be mentioned. The different biologicals should have their individual tuberculin luers unless the syringes are soaked in dichromate cleaning solution after each use. Otherwise, the active principles will be adsorbed and diagnostic chaos result.

Dr. Ray O. Carter, Los Angeles: Drs. Zwerling and Palmer have made a definite contribution in correlating roentgenographically evident, apparently early pulmonary lesions with a negative tuberculin test and a histoplasmin reaction which turned positive and in observing the onset of calcification in such lesions. As they stated, the exact specificity of the reaction to histoplasmin is secondary to the fact that calcifications due neither to tuberculosis nor coccidioidomycosis are present in numerous instances in the lungs. Complete proof may require identification of the organism. However, it appears safe to assume that histoplasmosis or an allied group of diseases is the cause of these calcifications. Pulmonary calcifications due to coccidioidomycosis have been authenticated by Smith and Aronsen and by Butt. No assumption appears to have been made by Palmer or Zwerling or Christie that the residual calcifications of histoplasmosis which are so prevalent are of clinical significance nor has this been shown to be true in coccidioidomycosis. Since they are so considered in tuberculosis, it is important to recognize that many of the calcifications found in roentgenograms of the chest are neither tuberculous in origin or of known present clinical importance. This knowledge would have been extremely useful during the period of assembly of the nation's military forces. However, the roentgenologic military surveys themselves gave an impetus which has furthered the more recent work of Palmer, Christie, Zwerling and others. Pathologic calcifications appear to be largely a sequel to avascularization and focal necrosis. As such they are quite nonspecific. Their significance depends largely on incidentally available distinctive features of their location and appearance and associated immunologic evidence. With fungus infections geographic considerations become important. The policy of most observers in the reporting of pulmonary calcifications appears to be conservative. This is natural, since these may be simulated by vascular shadows. This conservatism has also been furthered by the presumed tuberculous origin of the calcification, which makes one reluctant to identify smaller dubious ones. Under these influences the policy may well have become overconservative. Most physicians have seen pulmonary calcifications proved on incidentally obtained oblique roentgenograms which would have been accepted as vascular shadows on a simple survey film. It is of interest that histoplasmosis, like coccidioidomycosis and other diseases, was first recognized and typed by its severe manifestations and was later revealed to have a large, previously unrecognized substratum of benign involvement and an even broader one of subclinical manifestations. This appears to be true also of tuberculosis. Earlier studies of pulmonary calcifications are now of renewed interest. Conceptions of calcium metastasis of anergic or healed miliary tuberculosis now are less readily accepted, but these also may occur.

Dr. W. Edward Chamberlain, Philadelphia: This is an extraordinarily fine piece of work. In my capacity as Consultant, Division of Tuberculosis Control, United States Public Health Service, I have had an opportunity to follow its development and witness the care with which it has been handled. That it has great practical importance is obvious, for it has answered some questions that have bothered radiologists for thirty years. The authors have reported their observations with commendable conservatism. Perhaps this is necessary in cases in which evidence is circumstantial. But circumstantial evidence can be exceedingly convincing, and in this particular case it seems to me that the conclusions which the authors have suggested are thoroughly justified from every point of view.

Dr. Henry B. Zwerling, Berkeley, Calif.: One statement that did not belong in the paper, in my opinion, is that we have collected a few instances of splenic calcification in tuberculin-negative, histoplasmin-positive children. The only difficulty is that we cannot say just what that observation means because so far all these cases of splenic calcification involve pulmonary calcification. We expect pulmonary calcification in Kansas City, Mo., to be histoplasmin-positive; whether the splenic calcification is evidence of disseminated histoplasmosis cannot be stated.

Clinical Notes, Suggestions and New Instruments

SUBCONJUNCTIVAL HEMORRHAGE DURING THE ADMINISTRATION OF RUTIN

A Report of Two Cases

JOSEPH B. WOLFFE, M.D.
and
A. W. DANISH, M.D.
Philadelphia

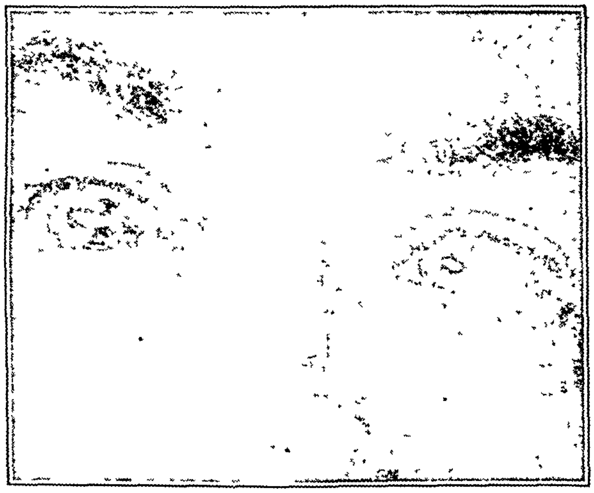
Rutin, a flavone glucoside first isolated in 1842, is found in many plants. Dr. James F. Couch of the Eastern Regional Research Laboratory, United States Department of Agriculture, noting the structural similarity of rutin to hesperidin, advanced the possibility of its use in the treatment of some forms of bleeding. As a result of a series of chemical investigations, he found that the unripe buckwheat leaf gave the highest yield of rutin, and this is the plant from which our present supply is extracted.

Rutin was given in initial doses of 60 mg. daily to a series of 66 patients in the course of a clinical investigation. In the four months during which this study has been followed, in 2 of the patients who were taking the rutin there developed subconjunctival hemorrhages. During the same period, only 1 patient of a much larger group being treated similarly (with the exception that they were not receiving rutin) and for similar conditions has shown this type of hemorrhage.

From the Wolffe Clinic and the Department of Medicine, Temple University School of Medicine.

REPORT OF CASES

CASE 1.—R. G., a dentist aged 46, gave a history of hypertension for fifteen years and of effort angina for one year. When first seen in March 1946 his blood pressure was 210 systolic and 125 diastolic. There was an area suggestive of old healed small hemorrhages in the right retina. The rest of the physical examination and laboratory studies were as expected in a case of long-standing hypertension (on a renal and atheromatous basis) with angina. This patient was started on rutin, 20 mg. three times a day, on March 12, 1946, in addition to other therapy. On April 9, 1946, there developed in his right eye a subconjunctival hemorrhage, which increased in size the following day (see the accompanying illustration). Further history revealed that he had had a similar, but less extensive, hemorrhage several years before A capillary fragility test performed on the day that the hemorrhage developed was well within normal limits (petechial index—Gothlin technic). The blood pressure was 185 systolic and 110 diastolic. In spite of the hemorrhage the dosage of rutin was increased to 50 mg. three times a day. On May 5, 1946 we received a communication stating that a similar hemorrhage had occurred the day before involving the same area. We then increased the rutin to 100 mg. three times a day, and to date there have been no recurrences.



Subconjunctival hemorrhage (case 1) appearing four weeks after start of rutin therapy.

CASE 2.—J. W., a physician aged 50, gave a history of detached left retina ten years previously and venous and arterial thrombosis in the right eye three years before The blood pressure was 145 systolic and 90 diastolic. In February 1946, after taking 60 mg. of rutin in twenty-four hours, a small subconjunctival hemorrhage appeared in the left eye. Nothing of this sort had ever before been experienced by this person. The patient's fragility test was normal. The patient discontinued rutin of his own accord. No hemorrhage has occurred since then.

COMMENT

The fact that hemorrhages occurred in patients whose capillary fragility was normal throws doubt on the relationship between the Gothlin index and the tendency to hemorrhage—at least in this particular type of bleeding. It would indicate that the Gothlin index is no criterion on which to predict this kind of hemorrhage.

In the first case, hemorrhage occurred in spite of the ingestion of 1,700 mg. of rutin within four weeks and recurred four weeks later, after an additional 4,200 mg. of the drug had been taken. When the dose was increased to 300 mg. a day no further hemorrhage occurred.

It is possible that early in the administration of rutin there is a period when there is an increased tendency to hemorrhage—a so-called vulnerable period. There is some experimental evidence for this phenomenon, both in our unpublished work on rutin in animals, and in Majovski's[1] work on hesperidin. This important phase needs further investigation.

Amounts of rutin as high as 60 to 150 mg. daily did not protect the patient in case 1 from subconjunctival hemorrhages. However, when the same patient was given still larger doses of rutin, he did not have further recurrences.

SUMMARY

Two cases of subconjunctival hemorrhage are reported; the first after approximately four and eight weeks of rutin therapy, the second after one day's administration of this drug.

1829 Pine Street.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

AN APPRECIATION

The Council on Physical Medicine desires to take this opportunity to express its feelings of gratitude and appreciation for the services of the following consultants, whose assistance in carrying out the work of the Council has been given so freely during the past year: Drs. Charles A. Bahn, Alvan Barach, Edward Bigg, Raymond Carhart, Milton B. Cohen, Clarence J. Gamble, H. G. Hansson, Le Grande Hardy, John S. Hibben, Alexander Hollaender, Alfred Lewy, A. M. Olsen, Stafford L. Osborne, Howard F. Polley, Scott N. Reger, Henry Schwerma, Khalil G. Wakim, Ralph Waters, Harold Westlake, Lieut. (jg) Eva Thompson and Mr. Luther Ramer.

Artificial Limbs.—Drs. Henry H. Kessler, Paul Klopsteg, Harry E. Mock, S. Perry Rogers, Paul B. Steele, J. B. Korrady, Joseph A. Spievak and David E. Stolpe.

Medical Aspects of Atomic Energy.—Drs. Kenneth S. Cole, L. F. Curtiss, Hymer L. Friedell, Shields Warren and Stafford L. Warren.

Audiometers and Hearing Aids.—Drs. Gordon Berry, Hallowell Davis, E. P. Fowler, W. E. Grove, Isaac H. Jones, Dean Lierle, Moses H. Lurie, Douglas Macfarlan, C. Stewart Nash, Paul E. Sabine and B. R. Shurly.

Contraceptive Devices.—Drs. N. J. Eastman, William W. Greulich, Joseph Hughes, Andrew C. Ivy, Walter J. Meek, Ephraim Shorr and Mr. R. R. Olin.

Educational Work.—Drs. Frances Baker, Robert L. Bennett, Benjamin Boynton, Earl C. Elkins, F. H. Ewerhardt, Richard Kovacs, Fred B. Moor, W. H. Northway, William Schmidt, Walter M. Solomon, Arthur L. Watkins, George D. Wilson and Walter J. Zeiter.

Electrocardiographs.—Drs. A. R. Barnes, George Fahr, Harold E. B. Pardee, William D. Stroud, Carl J. Wiggers and Frank N. Wilson.

Electroencephalographs—Drs. Percival Bailey, Edward J. Baldes, Stanley Cobb, Hallowell Davis and Frederic A. Gibbs.

Occupational Therapy.—Drs. Raymond B. Allen, Robert W. Johnson Jr., Winfred Overholser, Howard A. Rusk, William D. Stroud and Francis B. Trudeau.

Ophthalmic Devices.—Drs. Thomas D. Allen, S. Judd Beach, Conrad Berens, Frederick C. Cordes, Alfred Cowan, Walter B. Lancaster, William H. Luedde, Lawrence T. Post, Avery D. Prangen and Kenneth C. Swan.

Respirators.—Drs. Edward L. Compere, Charles F. McKhann and James L. Wilson.

Roentgen Rays and Radium.—Drs. William E. Chamberlain, Arthur C. Christie, Edwin C. Ernst, Gioacchino Failla, Fred M. Hodges, Robert R. Newell, Eugene P. Pendergrass, Ursus V. Portmann, Lauriston S. Taylor and J. L. Weatherwax.

SATURDAY, JUNE 21, 1947

THE CENTENNIAL SESSION

The great convention celebrating the one hundredth anniversary of the establishment of the American Medical Association held in Atlantic City last week, for which the Board of Trustees, the Centennial Committee and the headquarters staff of the Association had planned so long and so carefully, surpassed every hope and expectation. Those who were fortunate in attending this great session will long remember it as an epoch marking occasion.

Attendance

The registered attendance—15,667—represents by far the largest assemblage of physicians ever held anywhere in the world. When it is realized that the number includes about one in four of the Fellowship of the Association, who were the only physicians eligible to register except for foreign guests, the number of those attending is all the more remarkable. As a result of this tremendous registration, every one of the scientific sections and every exhibit had the continuous participation of a capacity audience. Indeed from some of the meetings and special functions it became necessary to turn away hundreds or even thousands of visitors.

Dinner for Associated Organizations

In The Journal of June 28 will appear the papers of Mr. Henning W. Prentis Jr. and Mr. Basil O'Connor, which were read to the audience at the dinner honoring the industries, the organizations and the professions associated with medicine. These addresses speak for themselves. Their significance was recognized. These pronouncements by great leaders in American industry and philanthropy will unquestionably be effective in indicating to the public the importance of the American way of life for the advancement of medical science and medical practice. In his extemporary address General Omar Bradley paid tribute to the contributions of the medical profession toward the winning of the war and in the great task of salvaging the wounded and the disabled in our military forces.

Religious Services

On Sunday morning, June 8, the National Broadcasting chain spread to the nation addresses by three great religious leaders, the Rev. Ralph Cooper Hutchison, President of Lafayette College, Easton, Pa.; Rabbi Joshua Loth Liebman of Boston, and Monsignor Fulton J. Sheen of Washington, D. C. These sermons were classical. After the broadcast the speakers delivered more extended addresses in the great convention hall. Here they spoke so eloquently, so beautifully and with such sincerity of the partnership that prevails between the minister of faith and the minister of healing that many of those who heard the addresses considered the occasion the outstanding event of the entire session.

The Centennial Stamp

On Monday morning a hoard of philatelists descended on Atlantic City to be present at the opening day's sale of the centennial stamp issued through cooperation of Postmaster General Robert E. Hannegan and the Post Office Department. The Journal in a recent editorial told the story of this stamp. Thousands of first day covers were made available, and this reminder of the services that the doctor gives was spread into every state. The Post Office Department issued 125,000,000 stamps. In the official presentation of the stamp by Assistant Postmaster General Joseph Lawler at the dinner of the House of Delegates on Monday night, Mr. Lawler stated that postmasters throughout the United States had ordered 80,000,000 of the stamps; 2,000,000 had been ordered for distribution in Atlantic City. This, he said, was apparently one of the most popular issues of stamps for special occasions developed by his department.

Exhibits

Unquestionably first in recognition by Fellows of the Association and by guests from all the countries of the world was the Scientific Exhibit. The mere listing of these exhibits or a reading of the descriptions of the exhibits which received the awards cannot convey the completeness, the elaborate character or the high scientific quality of these demonstrations of medical progress. Again and again those in attendance expressed the wish that these might be available throughout the year for graduate study in all parts of the country. Some of the foreign guests were amazed to learn that most of the exhibits would be shown merely for the one week at the annual session and would then not appear again. From the opening to the closing each day throngs of interested observers occupied every inch of available space at the exhibits and in the aisles.

The industries associated with medicine which provided the technical exhibits were also unanimous in their tribute to the arrangements and to the quality of the session. Many had failed to anticipate the immense audiences and began to exhaust their supplies by the third or fourth day, so that they were compelled to communicate with their home offices for additional samples, registration cards, pamphlets and even pencils. Many of the exhibitors had utilized the occasion to present historical demonstrations of progress in medicine's attack on disease. Possibly a compilation of the illustrations and the histories thus prepared may be gathered for a permanent pictorial history of medical progress.

General Medical Meetings

The great ballroom of the Atlantic City convention hall provides seating for 5,000 to 6,000 persons. The number in attendance on the general medical meetings was sufficient at all times to require that capacity. Such speakers as Florey, Seddon and Pickering no doubt did much to attract the audience, but the panel discussions and the papers reporting recent progress in medicine in many fields repaid many times those who attended.

At one of the sessions on Tuesday those present had opportunity to hear a message delivered in person by the Secretary of War, Robert P. Patterson, and the Assistant Secretary of the Navy for Air, John Nicholas Brown, who then proceeded to speak at a luncheon of the House of Delegates. Here the Secretary of War told of the plans for the advancement of the status of physicians in the armed forces, and the Navy representative discussed particularly the medical problems associated with aviation in war.

Opening Session

Many hundreds were turned away from the opening general session held on Tuesday night, June 10. The capacity audience assembled early to hear the magnificent concert of the Philadelphia Festival Orchestra under the direction of Alexander Hilsberg. Each of the selections was greeted by an ovation. The perfection of the performance is a tribute to the greatness and fame of this musical assemblage. At the conclusion of the concert the orchestra presented a distinct novelty —a march dedicated to the victory at Iwo Jima, composed by the President of the Association, Dr. Edward L. Bortz. Then came the program, which included not only the address of the President on "The Objectives of the American Medical Association," published in THE JOURNAL last week, but also presentation of the distinguished invited guests—more than 60 in number—who had come from all parts of the world, representing scientific progress in various medical specialties, the medical organizations of their countries or their governments. The great hall was decorated with the flags of all nations. The announcement by the chairman of the Board of Trustees, Dr. R. L. Sensenich, that honorary fellowship was awarded to each of these distinguished physicians was greeted by a rising of the entire audience in tribute to our guests.

The Foreign Visitors

As has been mentioned, more than 60 distinguished foreign physicians attended the meeting as invited guests who participated in programs of the general medical meetings and the scientific sections, and also those delegated by the governments of various nations and by the medical associations. Several of the physicians who attended were ambassadors of their governments to the United States. Others held a variety of governmental appointments. During the sessions of the House of Delegates the proceedings were interrupted from time to time for the introduction of these guests. The delegates from the British Medical Association, which included the chairman of their council, their secretary, their editor and the chairman of their Committee on International Relations, presented to the House of Delegates a gavel and a block made from the wood of a tree that had grown in Tavistock Square, now site of the home of the British Medical Association, but formerly occupied by the home of Charles Dickens. It was under this tree that he wrote many of his great novels. The delegate from China presented to the House a scroll painted on silk with a tribute to the advancement of medical science as a result of the efforts of American medicine. Many of the representatives of foreign governments presented brochures and scrolls especially prepared for the occasion. From Denmark came a medical book published in the earliest days of printing; from Switzerland a medal especially designed to commemorate the occasion, and indeed from every representative a special resolution or memorial congratulating the Association on 100 years of medical progress. On June 12 the Medical Services Foundation tendered a luncheon to the invited guests from abroad, at which Dr. Harry Guy Dain of the British Medical Association and Dr. Sven Forssman, representing Sweden, spoke of the importance of international relations in the advancement of medical care.

During the session, the House of Delegates approved participation of the American Medical Association in the World Medical Association and also cooperation with the Pan-American Medical Federation. Thus the Centennial Session served to give great impetus toward international relationships in medical science.

Again at the President's reception on Thursday night our distinguished foreign guests stood in three great reception lines, where visitors to the convention had opportunity to shake them by the hand, to meet them personally and to exchange a few words of personal greeting.

Scientific Sections

The program of the scientific sections was printed in the Convention Number of THE JOURNAL, May 3, and no doubt did much to attract the tremendous number of physicians who attended the meetings of the sections. Each of the scientific programs included at least one representative of a foreign country, several included two or three, and in addition an address delivered by a great leader of American medicine on one hundred years of progress in the specialty concerned. There were several symposiums and joint meetings of sections. More than 2,000 physicians attended the panel discussion on "Recent Advances in Treatment," which was a joint meeting of the Sections on Internal Medicine and Experimental Medicine and Therapeutics, this being held on the concluding day of the session. The great audience sat for several hours and submitted hundreds of questions, which were answered by the eight leaders in the field of medicine who participated in the panel.

President's Reception

Distinctive for the President's reception at this convention was the participation of two "name" orchestras, those of Tommy Tucker and Eddie Lane, who provided music alternately and continuously to a vast and colorful assemblage of physicians and their ladies. The three reception lines which greeted the visitors included a representative of the local committee and respectively the retiring President, the President and the President-Elect of the Association and of the Woman's Auxiliary. Included also, as has already been mentioned, were the invited guests of distinction and their wives. Testimony to the pleasure of the Fellows of the Association in meeting personally these representatives of American and foreign medicine was the length of the queues which formed and which for hours passed from one line to the next.

Fraternity, Alumni and Honorary Dinners

Throughout the session, but particularly on Wednesday and Thursday nights, dinners were held by alumni associations of our great medical colleges, by the great medical fraternities and by various honorary societies and other organizations, which attracted great numbers of convention visitors. One dinner of note was that given by the Passano Foundation to the officers and trustees of the Association, at which the Passano Award was given to Selman Waksman for his discovery of streptomycin and at which tribute was tendered to him by Sir Howard W. Florey. The dinner of the alumni association of Jefferson Medical College attracted between 600 and 700 guests. Alpha Omega Alpha at a dinner attended by hundreds conferred honorary membership on the invited guests. Many of the great industrial groups associated with the medical profession provided cocktail parties, receptions and dinners during the week. The W. B. Saunders Company tendered a dinner to the Board of Trustees and officers of the Association, at which there was an official presentation of the History of the Association, which they have published. Mead Johnson & Company provided a great dinner to celebrate awards for the exhibits of art, including painting, etching and sculpture.

Woman's Auxiliary

The Woman's Auxiliary of the American Medical Association now has more than 30,000 members. It has a potentiality for service to the American Medical Association in the field of public relations which will no doubt be utilized to the utmost in future plans. During the Centennial Celebration the organization held frequent meetings, luncheons and dinners distinguished by fine programs and maximum attendance. The headquarters of the Woman's Auxiliary is now permanently established in the headquarters office of the Association, and the Board of Trustees has planned for regular conferences with the directing bodies of the Auxiliary for complete coordination of effort.

Publicity—Press and Radio

Throughout the annual session there were broadcasts over the national chains and over local stations which kept the nation constantly aware of the great centennial meeting. At the Monday night dinner of the House of Delegates the Mutual Broadcasting System duplicated one of the broacasts in its series on "Stephen Graham: Family Doctor." The American Broadcasting Company provided a nationwide broadcast descriptive of the exhibits in which the President of the Association and the editor described the technical and scientific expositions. The chairman of the Board of Trustees, the President of the Association, Dr. Bortz following his inauguration and many others spoke at various times over nationwide networks. Some of the addresses will be published in forthcoming issues of *Hygeia.*

The press representatives were tendered a luncheon on the Saturday preceding the session, at which time they were provided with abstracts of the most important papers and with information concerning the special functions of the week. All were invited to attend the dinner to the associated industries and professions. Two press rooms were in continuous operation—one in the convention hall and the other in the Traymore Hotel, which housed the meetings of the House of Delegates. Daily articles were spread throughout the nation by representatives of the Associated Press, United Press, International News and by syndicated writers, as well as by individual representatives of many great newspapers and news magazines. Many periodicals of national circulation have celebrated the centennial by pictures related to the medical profession on their covers and by feature articles.

House of Delegates

Unfortunate perhaps were members of the House of Delegates, who were continuously in session from June 9 through June 12 except for one morning, at which time, incidentally, at least half of the membership of the House were occupied in reference committees. Such flavor of the session as they were able to gather was dependent on the visits to the House of Delegates by the distinguished invited guests and by the functions which took place at night. The problems most prominently confronting the House of Delegates concerned the future of the general practitioner, the reorganization of staffs of hospitals to provide for a service in general practice, the utilization of the total medical profession for any future military emergency, plans for the promotion of voluntary insurance against the costs of sickness and hospitalization, the provision of a supplemental meeting of the House of Delegates during the winter months and in association therewith a two day single general session designed particularly for the general practitioner, this to be arranged under the joint auspices of the Board of Trustees and the Council on Scientific Assembly. Using the technic of the propagandists Senator James E. Murray tried to divert the publicity interest from the advancement of medical science to his campaign for socialization of medicine. With the ineptness characteristic of the actions of this group the mass of publicity material sent to Atlantic City came directly into the hands of officers of the Association. The House of Delegates replied to Senator Murray unanimously, expressing again its opposition to his proposals. So comprehensive is the work of the American Medical Association that the reference committees charged with the report of the Board of Trustees and the Secretary, with the recommendations of the officers and with medical legislation and public relations took the entire available time of the members of the reference committees charged with examination of reports and action on resolutions in this field. Special reports on rural health, on convalescent care and that of the Committee on Emergency Medical Service were long and detailed and occupied many hours of time of members of the House. The executive session was concerned particularly with the final report of an interim committee on the public relations of the American Medical Association.

The proceedings of the House of Delegates will be published in THE JOURNAL during the next few weeks. Readers of THE JOURNAL are advised to follow the text of these proceedings as closely as possible, since the actions taken by the House of Delegates are vital to the further progress of the medical profession. The proceedings include, moreover, the beautiful messages presented to the House of Delegates by the President of the United States, by our invited guests and by officials of our own government.

The History of the Association

Through extraordinary efforts by the publisher, the History of the Association, which includes a general account of its progress, the lives of the presidents with a photograph and a signature for each, and a record of the growth of each of the councils, bureaus, publications and various agencies of the Association, was made available on Monday, June 9. The wide distribution of this work to libraries and to the public generally throughout the world will serve as a permanent memorial of one hundred years of progress of the American Medical Association. During these one hundred years the Association has reached in membership and in fellowship, in the number and quality of its publications, in its councils, bureaus and other departments, in its service to the medical profession, a recognized position of leadership in all the world.

As was said in the opening paragraph of this editorial, the celebration of the centennial was epochal. Fifty-years ago Dr. Nicholas Senn predicted that the one hundredth year would see a membership of perhaps 100,000 and would witness inventions and discoveries beyond the conception of his day. As was said by Dr. Edward L. Bortz, in his president's address, "His vision has proved correct." The centennial celebration brought the message of progress in addresses, in exhibits, in information to the public and in tribute rendered in music, in art, in religion and in science.

FLUOROSCOPIC DIAGNOSIS OF GASTRIC CANCER

In the early stages cancer of the stomach produces few or only slight symptoms. Many, perhaps most victims of gastric cancer do not seek medical advice before the cancer has advanced beyond surgical cure. For various reasons delay in diagnosis often occurs even if the patient is under medical care; in general the prognosis remains distressingly dismal. With the means at hand the only way to change the outlook is removal of the cancer much earlier than is now usual. This means of course that the cancer must be diagnosed in the early stages, even before it causes any symptoms.

The best if not the only practical method of excluding asymptomatic gastric cancer at present is fluoroscopy of the stomach, followed if indicated by x-ray, gastroscopic and other studies, as introduced by St. John, Swenson and Harvey.[1] By fluoroscopy they found 2 cases of early gastric carcinoma and 1 of lymphosarcoma in 2,413 persons in the cancer age, all apparently well and without any obvious gastrointestinal disturbances. In his important article on gastric cancer problems Barrett [2] points out that evaluation of this method will require examination of larger groups than 500 healthy people.

In their review of the diagnosis and the results of surgical excision of gastric cancer, Abrahamson and Hinton [3] urge that routine fluoroscopic and x-ray examinations of persons in the cancer age should be carried out more and more as the only means now available for the presymptomatic diagnosis of cancer of the stomach. Such studies should be included in periodic examinations in military and veteran services, in industries, of applicants for health and life insurance, and as a matter of routine on the hospital entrance of all patients above 40 years of age. They also urge that facilities be made available for fluoroscopy of the stomach of private patients over 40 in all economic groups. This suggestion is of course especially applicable to diagnostic and preventive cancer clinics.

Current Comment

THE PRESIDENT-ELECT, DR. ROSCOE LLOYD SENSENICH

In recognition of his long and outstanding service to the American Medical Association, Dr. Roscoe Lloyd Sensenich was elected by the House of Delegates to the position of President-Elect at the Centennial Celebration in Atlantic City. Dr. Sensenich has been Chairman of the Board of Trustees of the American Medical Association since 1945, has been a member of the Board of Trustees since 1937 and was a member of the House of Delegates continuously from 1931 to 1937. On frequent occasions he has represented the Association in public hearings before committees of Congress. Dr. Sensenich graduated from Rush Medical College in 1905, served internships at the Presbyterian and St. Joseph hospitals in Chicago under Dr. D. W. Graham and Dr. Nicholas Senn, and then did graduate work at medical centers in the United States and abroad. A native of Indiana, he is chief of the Department of Internal Medicine at the Memorial Hospital, South Bend, in which city he has resided for many years. He is a member of the staff of St. Joseph Hospital, president of the board of St. Joseph Tuberculosis Hospital, director of the South Bend Medical Laboratories and was a member of the Advisory Committee on Services to Crippled Children of the Indiana State Department of Public Welfare. He is a specialist certified by the American Board of Internal Medicine, a fellow of the American College of Physicians and a member of the Central Society for Clinical Research. He is a past president of St. Joseph County Medical Society, the Indiana State Medical Association and the Indiana Tuberculosis Association. During World War I Dr. Sensenich was a major in the Medical Corps, serving as chief of the medical service of an army general hospital; during World War II he was a member of the National Committee on Allocation of Medical Personnel to the Armed Forces, of the committee which cooperated with the National Advisory Council on Physical Fitness and of the Advisory Committee of Selective Service. During his incumbency in official positions in the Association Dr. Sensenich has devoted himself enthusiastically to its work. He has traveled widely to speak to state and county medical societies and has participated in conferences with other medical and related organizations and with leaders in many spheres of activity. His report with Dr. Ernest E. Irons on the relation of the roentgenologist, pathologist and anesthesiologist to the work of the hospital was a fundamental document in this disturbing situation. His election to the position of President-Elect is recognition of the efficiency that he has given to every activity in which he has participated.

Roscoe L. Sensenich, M.D.
President-Elect of the American Medical Association

TONSIL STUMPS

Tonsillectomy is the most frequent surgical procedure in the United States. Since it is made in many instances on an ambulatory basis and often by physicians without specialized surgical training, many physicians apparently consider it an operation requiring a minor degree of surgical skill. The results of analysis of the rate of recurrences of tonsillar growth after tonsillectomy indicate that tonsillectomy should command all the respect of a major operation.[1] The incomplete removal of tonsillar tissue and the subsequent formation of infected tonsil stumps are rather common. The Spuths[2] recently reported the presence of tonsil stumps in 80 per cent of 285 tonsillectomized patients. Instead of being relieved through tonsillectomy of their foci of infection, many patients continue to absorb bacteria and toxins from the tonsillar tissue left in the throat and are often systemically much worse off than prior to their operation. While there is drainage of infectious and toxic material from the external surface of the tonsils before tonsillectomy so that only a part of such harmful matter is absorbed into the organism, this route of escape becomes obliterated after tonsillectomy. for the infectious and toxic material contained in the usual tonsil stumps are covered by scar tissue. It is resorbed in its entirety through the lymphatics and veins and may cause, in addition to fatigue, heart palpitations, vague muscular pains, secondary infections and allergic complications in remote organs (polyarthritis, nephritis, endocarditis, asthma, chronic phlebitis). Sometimes the diagnosis of tonsil stumps cannot be made by an inspection of the tonsillar region because the retained tonsil tissue may be buried beneath a thick layer of scar tissue. However, as inflamed tissues, the presence of which is usual with tonsil stumps, are sensitive to pressure, tonsil stumps can be detected with reliability by exerting pressure either directly on the tonsillar scar tissue or externally from the angle of the lower jaw in the direction of the tonsillar fossa. Tonsils when functioning normally are protective organs and should not be removed. Definitely infected tonsils and especially tonsil stumps should be radically removed under general anesthesia and with adequate surgical technic and skill.

DISTINGUISHED SERVICE MEDAL

At the Centennial Session of the American Medical Association in Atlantic City, June 9-13, Dr. Henry Asbury Christian, Hersey professor of theory and practice of physic, emeritus, at Harvard Medical School, Boston, was nominated to receive the citation and the Distinguished Service Medal of the American Medical Association. Dr. Christian was born in Lynchburg, Va., in 1876. After graduating from Johns Hopkins University School of Medicine, Baltimore, in 1900 he was appointed assistant pathologist at the Boston City Hospital and from 1903 to 1907 taught pathology at Harvard Medical School. In 1908 he became Hersey professor of the theory and practice of physic, serving actively until 1939. Dr. Christian was dean of Harvard Medical School from 1908 to 1912. In 1942 he was recalled at Harvard and in 1943 served as clinical professor of medicine at Tufts College Medical School. From 1910 to 1939 he was physician in chief at the Peter Brent Brigham Hospital and from 1907 to 1912 was also physician in chief at the Carney Hospital. He was on the staff of Beth Israel Hospital in Boston, was a major in the medical reserve corps of the U. S. Army from 1918 to 1921, and for one year was resident chairman of the division of medical sciences of the National Research Council. Dr. Christian served the American Medical Association as secretary of the Section on Pathology and Physiology from 1903 to 1905, as chairman of the section from 1905 to 1907 and as a delegate from that section in 1909. In 1916-1917 he was secretary of the Section on Practice of Medicine and a delegate from this section in 1926 and 1927. He was president of the American Society for Clinical Investigation in 1919, of the Interstate Postgraduate Medical Association of North America in 1931 and of the Association of American Physicians in 1935. He is a member of many learned societies both here and abroad and has received honorary degrees from various universities.

Awarded Distinguished Service Medal

CHEMICAL BURNS OF THE HUMAN CORNEA

On the basis of 500 cases treated for chemical eye burns, McLaughlin[1] has observed that certain chemicals have a delaying action. Such chemical compounds frequently cause a loss of vision due to opacification of the cornea and adhesions of the conjunctiva following a symptom free period of several hours after accidental contact. The most notable observation is change in corneal structure produced by all alkaline and a few neutral organic compounds, but not by acidic compounds or those neutral chemicals which experience shows to be relatively harmless. The change in the corneal structure, as observed with the high power of the biomicroscope, reveals the presence of areas of opacity in the superficial layers of the corneal epithelium. The opaque areas are seen to be stained a faint green by fluorescein when observed by direct illumination. Studies by Carpenter and Smyth[2] suggest that the foreign compound initially is physically adsorbed on protein structures of the corneal epithelium. Following this a portion of the adsorbed chemical denatures cellular protein, resulting in necrosis. The remainder is liberated slowly with its chemical nature unchanged, to diffuse from the original site of adsorption into previously unaffected tissue. Instead of a delaying effect there is therefor progressive action which may spread to involve the entire depth of the epithelium down to Bowman's membrane, at which point irreparable damage to the tissue results. The greater number of the chemicals that behave in this way are alkaline. Attempts at neutralization of the acid substances failed in animal experiments[2] to give any amelioration of injury. The treatment that suggested itself in these cases was denudation or mechanical removal of the involved cells before a progressive action could be initiated. Immediate first aid, followed by long flushing with water and denuding where indicated, gave most gratifying results. Thus, of the 500 cases treated 456 (91.2 per cent) healed in forty-eight hours with no loss of vision; 37 (7.4 per cent) healed slowly but without loss of vision; 7 cases, or 1.5 per cent, healed with a residual loss of vision. McLaughlin emphasizes that this loss of vision was the result of inadequate preliminary care or such complicating factors as infected teeth or tonsils.

ORGANIZATION SECTION

PROCEEDINGS of the ATLANTIC CITY SESSION

MINUTES OF THE ANNUAL SESSION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN ATLANTIC CITY, JUNE 9-13, 1947

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 9

The House of Delegates convened in the Rose Room of Hotel Traymore, Boardwalk at Illinois Avenue, and was called to order at 10:30 a. m. by the Speaker, Dr. R. W. Fouts.

Preliminary Report of the Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, stated that 143 delegates had registered up to the present time and that the registration was steadily increasing.

Roll Call

The Speaker announced that a quorum was present and requested the Secretary to call the roll, which was done.

Distinguished Service Award

Dr. R. L. Sensenich, Chairman of the Board of Trustees, presented a report of the Board as follows:

The Committee on Distinguished Service Award of the American Medical Association submitted five names to the Board of Trustees.

In accordance with chapter VI, section 5, of the By-Laws, the Board has selected by ballot the following names for presentation to the House of Delegates in alphabetical order: Dr. Isaac Abt, Chicago; Dr. Alfred Blalock, Baltimore, and Dr. Henry A. Christian, Boston.

The Speaker appointed as tellers Dr. J. Wallace Hurff, New Jersey, Chairman; Dr. Mather Pfeiffenberger, Illinois; Dr. Jesse D. Hamer, Arizona; Dr. Guy W. Wells, Rhode Island, and Dr. Francis W. Savage, Minnesota.

The tellers spread the ballot and the Secretary announced that one hundred and fifty-four votes had been cast, of which Dr. Abt received fifty-three, Dr. Blalock thirty-one and Dr. Christian seventy. He added that one hundred and sixty-six delegates had answered the roll call.

The Speaker announced that since no one had received a majority of the votes cast, the House would proceed with a second ballot on which the name of the one receiving the least number of votes would be omitted.

The tellers spread the ballot, and the Secretary announced that one hundred and sixty-three votes had been cast, of which Dr. Abt received sixty-three and Dr. Christian one hundred.

The Speaker declared Dr. Henry A. Christian, Boston, who had received the majority of the votes cast, to be elected by the House of Delegates to receive the Distinguished Service Award of the American Medical Association.

Special Report of Board of Trustees

On request of the Speaker, the House of Delegates by unanimous consent granted permission to the Board of Trustees to present a special communication:

Communication from Dr. Olin West, Nashville, Tenn.: Dr. George F. Lull, Secretary, presented the following communication from Dr. Olin West, former Secretary and General Manager:

June 5, 1947

Dr. R. W. Fouts,
Speaker, House of Delegates,
American Medical Association,
Atlantic City, New Jersey.

Dear Doctor Fouts:

At this time when the American Medical Association is about to celebrate its one hundredth birthday my thoughts are all of the Association and of those who must establish its policies, those who are chosen to administer its affairs and the great body of physicians who compose its membership. The deepest and dearest desires of my heart are all for the continued and unbroken success of the Association in its efforts to serve and promote the great cause for which it has worked unceasingly for a century—the cause of medicine and its service to humanity.

It is one of the greatest disappointments of my life that I am denied the privilege of attending the great Centennial Celebration, of looking in on the meetings of the House of Delegates and of the Scientific Assembly, of viewing the exhibits and of greeting and shaking the friendly hands of many of those whom it has been my pleasure to see at annual sessions year after year.

I cannot refrain from asking you, as Speaker of the House of Delegates, to convey to the members of that body, the officers of the Association, the members of its Councils and Committees and its administrative personnel an expression of my high regard and of my gratitude for their many helpful kindnesses to me during the years when it was my privilege to be associated with them in efforts to carry on the great work of a great organization.

With unswerving adherence to the principle for which the Association has always stood and with steadfast devotion to the highest ideals and the worthiest professional traditions, and through the efforts of those who will succeed the men and women who now are serving and those who have served before them with such devotion, we may all expect with confidence that the next hundred years will be best until the third hundred has been completed.

May the Centennial Celebration be a glorious occasion!

Sincerely yours,
Olin West.

Dr. E. L. Henderson, Trustee, presented the report of a special committee appointed by the Board of Trustees, as follows:

In view of the fact that Dr. Olin West had been elected President-Elect by the House of Delegates at the annual session held in San Francisco in July 1946, and that he served for approximately nine months and was compelled to resign on account of ill health, the committee of the Board recommends that one of the medals presented to retiring Presidents be appropriately engraved and presented to Dr. West.

E. L. Henderson, Chairman.
John H. Fitzgibbon.

On motion of Dr. Louis A. Buie, Section on Gastro-Enterology and Proctology, seconded by Dr. H. B. Everett, Tennessee, and carried, the recommendation of the special committee of the Board was adopted.

It was moved by Dr. E. H. Cary, Texas, seconded by several and carried, that the Secretary be instructed to send to Dr. West a suitable telegram, expressing the sentiment and feeling of the members of the House of Delegates for him and that the telegram be arranged to be sent as a permanent resolution of our gratitude.

Adoption of Proceedings of Supplemental Session in Chicago, 1946

On motion of Dr. George W. Kosmak, New York, seconded by several and carried, the proceedings of the supplemental session of the House of Delegates held in December 1946 were adopted as printed and sent officially to members of the House.

Address of Speaker, Dr. R. W. Fouts

The Vice Speaker, Dr. F. F. Borzell, Pennsylvania, presided while the Speaker of the House read his address, which was referred to the Reference Committee on Reports of Officers and which reads as follows:

Mr. Speaker, Members of the House of Delegates and Guests:

At this Centennial Celebration of the American Medical Association, may I first tender my tribute to those who preceded me in this honored office. The previous speakers of the House of Delegates of the American Medical Association have included Dr. Hubert Work, a Secretary of the Interior and a former President of the American Medical Association; Dr. Dwight H. Murray of Syracuse, N. Y., whose untimely death prevented his occupancy of the office for more than an exceedingly short space of time; Dr. Fred C. Warnshuis, a secretary of the Michigan State Medical Society and later of the California State Medical Society; Dr. Nathan B. Van Etten, a former member of this House and later President of the American Medical Association, and Dr. Harrison H. Shoulders, a secretary of the Tennessee State Medical Society and now President of the American Medical Association. As I call to mind the integrity, the loyalty and the dignity with which they filled this office, I feel that the standard established by them may well be emulated by all who follow.

For many years the President of the American Medical Association presided over this representative body. As the responsibilities and interests of the Association grew, the House of Delegates decided to elect its presiding officer, who was designated as the Chairman. Shortly thereafter the name was changed to Speaker.

Those who occupied the position in the formative years were accustomed to make addresses in which they discussed problems currently facing the Association and made recommendations with reference to future policies and activities. Without doubt, some of these suggestions contributed in great measure to the advancement of the affairs of the Association and the attainment of its objectives.

However, after some years it became apparent to the House of Delegates that these functions were inherent in the office of the President and President-Elect, so that by custom and practice the Speaker of the House of Delegates now limits his opening address to problems dealing with the conduct of the representative body itself and with the customary tribute to those former members of the House of Delegates who have died during the preceding year.

At previous meetings of the House of Delegates I have suggested certain changes in its conduct. These were referred to the Reference Committee on Rules and Order of Business, which recommended their adoption, and the House has seen fit to give its unanimous approval to them. These recommendations have included the restriction of certain areas in the meeting place to delegates alone and the conduct of elections by ballot. The introduction of these changes has seemed to improve both the efficiency of the action of this House of Delegates and the manifestation of its wishes.

There comes before the House of Delegates at this session a proposed revision of the Constitution and By-Laws. As Speaker, I should call your attention particularly to that section of the revision which deals with the composition of the House of Delegates during an executive session and with the limitation on the attendance at such sessions. By its very nature, an executive session of the House of Delegates is concerned with matters vitally important to the life and welfare of the Association. It would therefore seem fitting that such considerations be conducted with the greatest degree of decorum and without the possibility of extraneous influences manifesting themselves before the House of Delegates shall have had opportunity to indicate by its vote the decision it wishes to make.

NEW MEMBERS

Several physicians are making their first appearance as members of this House at this meeting. In order that they may be properly identified, I shall ask them to rise and to remain standing as their names are called. I want to extend to these new members a hearty welcome and to assure each one prompt recognition when he rises to participate in the discussion of any question or other deliberation of this body.

IN MEMORIAM

The Speaker announced that it was now fitting that the House listen to the calling of the names of those who formerly held membership in the House of Delegates and who are no longer with us and then read the list as follows (the dates following the names indicate years of service in the House or as officers of the Association):

Charles G. Abell, Vermont, 1935-1936.
Reuben B. Anderson, Texas, 1934-1935; 1946.
John Andrew, Colorado, 1938-1939; 1941-1944.
Thomas E. Carmody, Colorado, 1927-1928.
Ernest D. Chipman, San Francisco, Section on Dermatology, 1915-1916.
James T. Christison, St. Paul, Section on Diseases of Children, 1918; Minnesota, 1934-1938.
Roland C. Connor, Isthmian Canal Zone, 1926.
A. Bennett Cooke, Tennessee, 1911-1913; member Judicial Council, 1911-1918.
Hatch W. Cummings, Texas, 1930.
Thomas Dorbandt, Texas, 1926.
Judson D. Dowling, Alabama, 1919; 1921-1922.
Wells P. Eagleton, New Jersey, 1924-1926; 1939-1940; 1942-1944.
James M. Flynn, New York, 1938-1941; 1943-1946.
Alfred I. Folsom, Texas, 1933.
William Hale, New York, 1944-1945.
William D. James, North Carolina, 1926-1927.
William S. Lindsay, Kansas, 1919-1920.
Frank R. Mount, Oregon, 1945.
John W. Preston, Virginia, 1927-1931.
Dennett L. Richardson, Rhode Island, 1913.
H. Joseph Rock, South Dakota, 1904; 1907-1908.
Carl R. Steinke, Ohio, 1935; 1937-1945.
F. Leslie Sullivan, New York, 1944-1946.
Samuel D. Swope, New Mexico, 1913; 1915-1916.
Michael A. Tighe, Massachusetts, 1938.
Marion Trueheart, Kansas, 1911.
Richard Frank Werner, Wisconsin, 1911.
Daniel J. Williams, Mississippi, 1904-1905.
Elbert G. Wood, Tennessee, 1930-1946.

The House observed a moment of silence in tribute to the deceased physicians.

REFERENCE COMMITTEES

In the appointment of reference committees, your Speaker has endeavored to give just representation to every state, taking into consideration the representation accorded each state on the various Councils and those members who have served on interim committees. Members who have duties in addition to their functions as delegates have likewise been spared the added burden of extra committee work.

The Speaker requested authorization to appoint three extra reference committees, one on Executive Session, one on General Practice of Medicine and the third on Emergency Medical Service. It was moved by Dr. Walter E. Vest, West Virginia, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, that the Speaker be authorized to appoint the extra reference committees requested.

Reference Committees

The personnel of all reference committees as appointed by the Speaker is as follows:

SECTIONS AND SECTION WORK

Roy B. Henline, Section on Urology, Chairman.
Edgar V. Allen, Section on Experimental Medicine and Therapeutics.
Burt R. Shurly, Section on Laryngology, Otology and Rhinology.
Lowell S. Goin, California.
Scott Lord Smith, New York.

RULES AND ORDER OF BUSINESS

James Stevenson, Oklahoma, Chairman.
William F. Costello, New Jersey.
James Beebe, Delaware.
Raymond L. Zech, Washington.
George A. Woodhouse, Ohio.

MEDICAL EDUCATION

George W. Kosmak, New York, Chairman.
Joseph D. McCarthy, Nebraska.
Thomas S. Cullen, Maryland.
William D. Stovall, Wisconsin.
A. W. Adson, Minnesota.

ORGANIZATION SECTION

PROCEEDINGS of the ATLANTIC CITY SESSION

MINUTES OF THE ANNUAL SESSION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN ATLANTIC CITY, JUNE 9-13, 1947

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 9

The House of Delegates convened in the Rose Room of Hotel Traymore, Boardwalk at Illinois Avenue, and was called to order at 10:30 a. m. by the Speaker, Dr. R. W. Fouts

Preliminary Report of the Reference Committee on Credentials

Dr. G. Henry Mundt, Chairman, stated that 143 delegates had registered up to the present time and that the registration was steadily increasing.

Roll Call

The Speaker announced that a quorum was present and requested the Secretary to call the roll, which was done.

Distinguished Service Award

Dr. R. L. Sensenich, Chairman of the Board of Trustees, presented a report of the Board as follows:

The Committee on Distinguished Service Award of the American Medical Association submitted five names to the Board of Trustees.

In accordance with chapter VI, section 5, of the By-Laws, the Board has selected by ballot the following names for presentation to the House of Delegates in alphabetical order: Dr. Isaac Abt, Chicago; Dr. Alfred Blalock, Baltimore, and Dr. Henry A. Christian, Boston.

The Speaker appointed as tellers Dr. J. Wallace Hurff, New Jersey, Chairman; Dr. Mather Pfeiffenberger, Illinois; Dr. Jesse D. Hamer, Arizona; Dr. Guy W. Wells, Rhode Island, and Dr. Francis W. Savage, Minnesota.

The tellers spread the ballot and the Secretary announced that one hundred and fifty-four votes had been cast, of which Dr. Abt received fifty-three, Dr. Blalock thirty-one and Dr. Christian seventy. He added that one hundred and sixty-six delegates had answered the roll call.

The Speaker announced that since no one had received a majority of the votes cast, the House would proceed with a second ballot on which the name of the one receiving the least number of votes would be omitted.

The tellers spread the ballot, and the Secretary announced that one hundred and sixty-three votes had been cast, of which Dr. Abt received sixty-three and Dr. Christian one hundred.

The Speaker declared Dr. Henry A. Christian, Boston, who had received the majority of the votes cast, to be elected by the House of Delegates to receive the Distinguished Service Award of the American Medical Association.

Special Report of Board of Trustees

On request of the Speaker, the House of Delegates by unanimous consent granted permission to the Board of Trustees to present a special communication:

Communication from Dr. Olin West, Nashville, Tenn.: Dr. George F. Lull, Secretary, presented the following communication from Dr. Olin West, former Secretary and General Manager:

June 5, 1947

Dr. R. W. Fouts,
Speaker, House of Delegates,
American Medical Association,
Atlantic City, New Jersey.

Dear Doctor Fouts:

At this time when the American Medical Association is about to celebrate its one hundredth birthday my thoughts are all of the Association and of those who must establish its policies, those who are chosen to administer its affairs and the great body of physicians who compose its membership. The deepest and dearest desires of my heart are all for the continued and unbroken success of the Association in its efforts to serve and promote the great cause for which it has worked unceasingly for a century—the cause of medicine and its service to humanity.

It is one of the greatest disappointments of my life that I am denied the privilege of attending the great Centennial Celebration, of looking in on the meetings of the House of Delegates and of the Scientific Assembly, of viewing the exhibits and of greeting and shaking the friendly hands of many of those whom it has been my pleasure to see at annual sessions year after year.

I cannot refrain from asking you, as Speaker of the House of Delegates, to convey to the members of that body, the officers of the Association, the members of its Councils and Committees and its administrative personnel an expression of my high regard and of my gratitude for their many helpful kindnesses to me during the years when it was my privilege to be associated with them in efforts to carry on the great work of a great organization.

With unswerving adherence to the principle for which the Association has always stood and with steadfast devotion to the highest ideals and the worthiest professional traditions, and through the efforts of those who will succeed the men and women who now are serving and those who have served before them with such devotion, we may all expect with confidence that the next hundred years will be best until the third hundred has been completed.

May the Centennial Celebration be a glorious occasion!

Sincerely yours,
Olin West.

Dr. E. L. Henderson, Trustee, presented the report of a special committee appointed by the Board of Trustees, as follows:

In view of the fact that Dr. Olin West had been elected President-Elect by the House of Delegates at the annual session held in San Francisco in July 1946, and that he served for approximately nine months and was compelled to resign on account of ill health, the committee of the Board recommends that one of the medals presented to retiring Presidents be appropriately engraved and presented to Dr. West.

E. L. Henderson, Chairman.
John H. Fitzgibbon.

On motion of Dr. Louis A. Buie, Section on Gastro-Enterology and Proctology, seconded by Dr. H. B. Everett, Tennessee, and carried, the recommendation of the special committee of the Board was adopted.

It was moved by Dr. E. H. Cary, Texas, seconded by several and carried, that the Secretary be instructed to send to Dr. West a suitable telegram, expressing the sentiment and feeling of the members of the House of Delegates for him and that the telegram be arranged to be sent as a *permanent resolution of our* gratitude.

Adoption of Proceedings of Supplemental Session in Chicago, 1946

On motion of Dr. George W. Kosmak, New York, seconded by several and carried, the proceedings of the supplemental session of the House of Delegates held in December 1946 were adopted as printed and sent officially to members of the House.

Address of Speaker, Dr. R. W. Fouts

The Vice Speaker, Dr. F. F. Borzell, Pennsylvania, presided while the Speaker of the House read his address, which was referred to the Reference Committee on Reports of Officers and which reads as follows:

Mr. Speaker, Members of the House of Delegates and Guests:

At this Centennial Celebration of the American Medical Association, may I first tender my tribute to those who preceded me in this honored office. The previous speakers of the House of Delegates of the American Medical Association have included Dr. Hubert Work, a Secretary of the Interior and a former President of the American Medical Association; Dr. Dwight H. Murray of Syracuse, N. Y., whose untimely death prevented his occupancy of the office for more than an exceedingly short space of time; Dr. Fred C. Warnshuis, a secretary of the Michigan State Medical Society and later of the California State Medical Society; Dr. Nathan B. Van Etten, a former member of this House and later President of the American Medical Association, and Dr. Harrison H. Shoulders, a secretary of the Tennessee State Medical Society and now President of the American Medical Association. As I call to mind the integrity, the loyalty and the dignity with which they filled this office, I feel that the standard established by them may well be emulated by all who follow.

For many years the President of the American Medical Association presided over this representative body. As the responsibilities and interests of the Association grew, the House of Delegates decided to elect its presiding officer, who was designated as the Chairman. Shortly thereafter the name was changed to Speaker.

Those who occupied the position in the formative years were accustomed to make addresses in which they discussed problems currently facing the Association and made recommendations with reference to future policies and activities. Without doubt, some of these suggestions contributed in great measure to the advancement of the affairs of the Association and the attainment of its objectives.

However, after some years it became apparent to the House of Delegates that these functions were inherent in the office of the President and President-Elect, so that by custom and practice the Speaker of the House of Delegates now limits his opening address to problems dealing with the conduct of the representative body itself and with the customary tribute to those former members of the House of Delegates who have died during the preceding year.

At previous meetings of the House of Delegates I have suggested certain changes in its conduct. These were referred to the Reference Committee on Rules and Order of Business, which recommended their adoption, and the House has seen fit to give its unanimous approval to them. These recommendations have included the restriction of certain areas in the meeting place to delegates alone and the conduct of elections by ballot. The introduction of these changes has seemed to improve both the efficiency of the action of this House of Delegates and the manifestation of its wishes.

There comes before the House of Delegates at this session a proposed revision of the Constitution and By-Laws. As Speaker, I should call your attention particularly to that section of the revision which deals with the composition of the House of Delegates during an executive session and with the limitation on the attendance at such sessions. By its very nature, an executive session of the House of Delegates is concerned with matters vitally important to the life and welfare of the Association. It would therefore seem fitting that such considerations be conducted with the greatest degree of decorum and without the possibility of extraneous influences manifesting themselves before the House of Delegates shall have had opportunity to indicate by its vote the decision it wishes to make.

NEW MEMBERS

Several physicians are making their first appearance as members of this House at this meeting. In order that they may be properly identified, I shall ask them to rise and to remain standing as their names are called. I want to extend to these new members a hearty welcome and to assure each one prompt recognition when he rises to participate in the discussion of any question or other deliberation of this body.

IN MEMORIAM

The Speaker announced that it was now fitting that the House listen to the calling of the names of those who formerly held membership in the House of Delegates and who are no longer with us and then read the list as follows (the dates following the names indicate years of service in the House or as officers of the Association):

Charles G. Abell, Vermont, 1935-1936.
Reuben B. Anderson, Texas, 1934-1935; 1946.
John Andrew, Colorado, 1938-1939; 1941-1944.
Thomas E. Carmody, Colorado, 1927-1928.
Ernest D. Chipman, San Francisco, Section on Dermatology, 1915-1916.
James T. Christison, St. Paul, Section on Diseases of Children, 1918; Minnesota, 1934-1938.
Roland C. Connor, Isthmian Canal Zone, 1926.
A. Bennett Cooke, Tennessee, 1911-1913; member Judicial Council, 1911-1918.
Hatch W. Cummings, Texas, 1930.
Thomas Dorbandt, Texas, 1926.
Judson D. Dowling, Alabama, 1919; 1921-1922.
Wells P. Eagleton, New Jersey, 1924-1926; 1939-1940; 1942-1944.
James M. Flynn, New York, 1938-1941; 1943-1946.
Alfred I. Folsom, Texas, 1933.
William Hale, New York, 1944-1945.
William D. James, North Carolina, 1926-1927.
William S. Lindsay, Kansas, 1919-1920.
Frank R. Mount, Oregon, 1945.
John W. Preston, Virginia, 1927-1931.
Dennett L. Richardson, Rhode Island, 1913.
H. Joseph Rock, South Dakota, 1904; 1907-1908.
Carl R. Steinke, Ohio, 1935; 1937-1945.
F. Leslie Sullivan, New York, 1944-1946.
Samuel D. Swope, New Mexico, 1913; 1915-1916.
Michael A. Tighe, Massachusetts, 1938.
Marion Trueheart, Kansas, 1911.
Richard Frank Werner, Wisconsin, 1911.
Daniel J. Williams, Mississippi, 1904-1905.
Elbert G. Wood, Tennessee, 1930-1946.

The House observed a moment of silence in tribute to the deceased physicians.

REFERENCE COMMITTEES

In the appointment of reference committees, your Speaker has endeavored to give just representation to every state, taking into consideration the representation accorded each state on the various Councils and those members who have served on interim committees. Members who have duties in addition to their functions as delegates have likewise been spared the added burden of extra committee work.

The Speaker requested authorization to appoint three extra reference committees, one on Executive Session, one on General Practice of Medicine and the third on Emergency Medical Service. It was moved by Dr. Walter E. Vest, West Virginia, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, that the Speaker be authorized to appoint the extra reference committees requested.

Reference Committees

The personnel of all reference committees as appointed by the Speaker is as follows:

SECTIONS AND SECTION WORK

Roy B. Henline, Section on Urology, Chairman.
Edgar V. Allen, Section on Experimental Medicine and Therapeutics.
Burt R. Shurly, Section on Laryngology, Otology and Rhinology.
Lowell S. Goin, California.
Scott Lord Smith, New York.

RULES AND ORDER OF BUSINESS

James Stevenson, Oklahoma, Chairman.
William F. Costello, New Jersey.
James Beebe, Delaware.
Raymond L. Zech, Washington.
George A. Woodhouse, Ohio.

MEDICAL EDUCATION

George W. Kosmak, New York, Chairman.
Joseph D. McCarthy, Nebraska.
Thomas S. Cullen, Maryland.
William D. Stovall, Wisconsin.
A. W. Adson, Minnesota.

LEGISLATION AND PUBLIC RELATIONS

Thomas P. Murdock, Connecticut, Chairman.
Thomas A. McGoldrick, New York.
William M. Skipp, Ohio.
Lloyd Noland, Alabama.
Forrest J. Pinkerton, Hawaii.

HYGIENE AND PUBLIC HEALTH

Walter E. Vest, West Virginia, Chairman.
James P. Wall, Mississippi.
Walter P. Anderton, New York.
Leonce J. Kosminsky, Arkansas.
James A. Crabtree, U. S. Public Health Service.

AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

Britton E. Pickett Sr., Texas, Chairman.
L. G. Christian, Michigan.
Allen H. Bunce, Georgia.
Homer Lee Pearson Jr., Florida.
Alfred S. Giordano, Indiana.

REPORTS OF OFFICERS

James R. Reuling, New York, Chairman.
Edward N. Roberts, Idaho.
James Q. Graves, Louisiana.
William H. Halley, Colorado.
Deering G. Smith, New Hampshire.

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Elmer Hess, Pennsylvania, Chairman.
Thomas F. Thornton, Iowa.
Allen G. Rice, Massachusetts.
Albert A. Gartner, New York.
Theodore H. Harwood, Vermont.

CREDENTIALS

G. Henry Mundt, Illinois, Chairman
A. P. Nachtwey, North Dakota.
H. B. Everett, Tennessee.
Charles F. Strosnider, North Carolina.
Raymond F. Peterson, Montana.

MISCELLANEOUS BUSINESS

James Z. Appel, Pennsylvania, Chairman.
Stephen R. Monteith, New York.
John W. Cline, California.
Edward H. McLean, Oregon.
Hugh P. Smith, South Carolina.

EXECUTIVE SESSION

Leland S. McKittrick, Massachusetts, Chairman.
Rollo K. Packard, Illinois.
Edgar P. McNamee, Ohio.
Charles L. Shafer, Pennsylvania.
Howard R. Dudgeon, Texas.
Clark Bailey, Kentucky.
H. B. Mulholland, Virginia.

GENERAL MEDICAL PRACTICE

Wingate M. Johnson, North Carolina, Chairman.
Thomas K. Gruber, Michigan.
A. R. McComas, Missouri.
Howard E. Griffin, Section on General Practice of Medicine.
H. G. Hamer, Indiana.
E. Vincent Askey, California.
Forrest L. Loveland, Kansas.

EMERGENCY MEDICAL SERVICE

Charles H. Phifer, Illinois, Chairman.
Herbert P. Ramsey, District of Columbia.
James R. McVay, Missouri.
Frank L. Cole, U. S. Army.
Morton D. Willcutts, U. S. Navy.
Thomas A. Foster, Maine.
George P. Johnston, Wyoming.

TELLERS

J. Wallace Hurff, New Jersey, Chairman.
Mather Pfeiffenberger, Illinois.
Jesse D. Hamer, Arizona.
Guy W. Wells, Rhode Island.
Francis W. Savage, Minnesota.

SERGEANTS AT ARMS

Frank E. Reeder, Michigan, Chairman.
H. Russell Brown, South Dakota.
Moreton J. Thorpe, Nevada.

Address of President

The Speaker resumed the chair and declared the next order of business to be the address of President Harrison H. Shoulders.

Dr. Shoulders delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker, Members of the House of Delegates and Guests:

For the last nine years it has been my duty and privilege to address this House of Delegates at its opening session. The realization that this is my last scheduled appearance before you stimulates emotions of satisfaction and regret.

This House of Delegates has been gracious and generous to me through all these years. For these considerations I am grateful beyond my power to express. Serving the Association in several different capacities has been a rich experience. This is especially true with respect to my service as President-Elect and as President.

I have been afforded the opportunity to meet with the Board of Trustees each quarter and with the Executive Committee of the Board each month. These privileges have enabled me to become familiar with the efficient and devoted services which these men render to this Association as well as to members of the medical profession at large.

I have also had opportunity to become more familiar with the operation of the several departments, councils and bureaus of the Association and better acquainted with the persons who carry on the many activities of this Association. And I want to say now, as a matter of opinion and conviction, that the affairs of this Association are in good order. They are well administered by capable persons who are loyal to the principles established by this House of Delegates.

By the gracious hospitality of many state and local medical societies in various parts of the country, I have had the privilege of meeting many members and Fellows in their home environments. I have discussed with them, and have become better acquainted with, their local problems and their points of view.

I have had the opportunity to meet with many nonmedical organizations, notably the American Legion and various farm groups. The leaders of these organizations are concerned with the same problems which are of deep concern to the medical profession. I have also observed on the part of those groups an increasing respect for the attitudes and policies of this Association in matters concerned with medical care.

These experiences and many others which I might mention have greatly enriched my life and given me a broader understanding of the many problems concerned with medical care and an acquaintance with many different points of view, both professional and nonprofessional.

These experiences have also increased my appreciation of the philosophy expressed by the great physician-philosopher Galen about eighteen hundred years ago to the effect that "Every organism is a biologic whole and every part of it is related to every other part." That philosophy applies to this organization with the same force and aptness as it does to a single organism.

This meeting is dedicated to the celebration of the hundredth birthday of this Association. It is unnecessary for me to discuss the various steps that have been taken in achieving the progress of medicine in this period, for several reasons. For instance: A history of the Association has been written and is ready for distribution. The Council on Scientific Assembly has arranged for the presentation of several addresses dealing with the progress that has been made in the many different branches of medicine. The Bureau of Exhibits has arranged many displays designed to portray something of this progress. Furthermore, it is not possible to describe and portray in the limited time available all the progress that has taken place in the science and art of medicine in this period. It is also impossible to appraise accurately what this medical progress has meant to the progress of civilization. Suffice to say that the present state of civilization could not have been achieved without the aid and benefit of medical progress.

In the contemplation of the progress and achievements of medicine there is one fact which stands out prominently, and that is that the changes which have taken place in the knowledge, technics and tools of medicine have not brought about a change in the philosophy of medicine. It has remained the same. There has been no need for change. The philosophy of medicine has been, and still is, a philosophy of progress, a progress which is restricted only by prudence and caution. It requires that the value of the new be tested and proved before it is adopted. It is a philosophy of service. It places service to humanity above all other considerations. It is a philosophy of freedom. It recognizes the dignity and importance of human individuality and that it is in an atmosphere of freedom that this individuality finds opportunity for its highest forms of expression in happiness and achievement.

It seems to me it would be appropriate for this House of Delegates at this Centennial Celebration to take action to rededicate the Association to the philosophy which has inspired and guided it throughout the first century of its existence.

The problems which were encountered by our predecessors varied widely in character and importance, but the method of approach to their solution has remained the same. It is characterized by diligence in the search for knowledge and truth, by diligence and perseverance in the acquisition of skills for applying knowledge to the needs of mankind. With this knowledge came wisdom—wisdom in the use of knowledge and skill.

The problems which face medical practitioners today are different in character from those which our predecessors encountered. Yet the fundamental principles they used still apply. It is important for us to remember that environments, technics and tools may change but that fundamental principles do not change. They are eternal.

Paradoxical as it may seem, many of the problems which are of immediate concern to members of the medical profession are due, in large measure, to the progress that has taken place in the science and technology of medicine. It has always been true that progress in any line brings new problems in its wake. This is especially true of the progress that has taken place in this field. These new problems are chiefly economic in character.

When appendicitis was treated largely by the administration of opium pills and the application of poultices to the abdomen, the cost of administering such treatment was low but the resulting mortality was high. When the physician acquired an understanding of the disease and perfected a technic for its proper treatment, the mortality from the disease went down to a low level but the cost of treatment went up. When diabetes was treated largely by diet and the administration of codeine, the cost of such treatment was low but the mortality was high. The diabetic patient lingered in discomfort for a relatively short while. But when the members of the profession acquired an understanding of the disease and developed a specific method for its treatment and management, diabetic patients were given an almost normal life expectancy in comfort and usefulness. Thus the problems in medical economics have been brought to the forefront.

Economics is a subject which is widely discussed but poorly understood. The simplest definition of the subject, it seems to me, is this: "Economics is a study of the means by which the people obtain the goods and services they need and/or desire."

Economics obtained long before finance existed. In reality, finance is nothing more or less than a tool of economics. Barter between individuals or nations is an economic, not a financial, transaction. Medical economics is concerned, of course, with the means by which the people obtain the medical services they need and/or desire. It is concerned not only with the financing of medical care but with its quality and availability.

For some years the Association has devoted a great deal of attention to many phases of this question. The report of the Council on Medical Service will indicate the measure of effort that has been exerted and the remarkable progress that has been made toward the solution of that phase of the problem which has to do with the financing of medical care.

The phase of the problem which is concerned with the quality and availability of the medical care the people need and/or desire is more complicated and more difficult of solution. There are many different opinions as to the cause or causes which have operated to bring it about. There are also many different opinions as to the remedy or remedies that should be applied to it.

There are areas in the United States in which it is difficult for persons to obtain the type and quality of medical service they need and/or desire. These areas in the main are thinly populated, and the number of persons involved is not large in proportion to the total population of the nation. These problems also have arisen as a result of the progress that has taken place in the science and technics of medicine and as a result of the changes that have occurred in the whole pattern of American life. The slightest study of the subject is sufficient to convince any one that the deficiencies in the availability of medical care are limited largely to the field commonly referred to as "general practice." It is generally considered that 85 per cent of the conditions for which persons seek medical advice can be diagnosed and treated properly and effectively by a good general practitioner. But only about 60 per cent of physicians are general practitioners. The availability to the population of the various services rendered by specialists is more nearly, if not completely, adequate, under modern methods of transportation than are the services of general practitioners. It is apparent therefore that the immediate and most urgent needs are concerned with increasing the availability of the services of general practitioners.

There are many different opinions as to the possible cause or causes of this maladjustment and the possible remedy or remedies which should be applied:

1. It is urged in some quarters that the number of medical graduates is too small and that it should be increased by many thousands. The evidence presented so far in support of this contention does not convince one that such action would solve the problems immediately or later.

2. It has been said that the cause of the maldistribution of physicians and services is due largely to financial considerations on the part of physicians. The evidence in support of this assertion is not convincing, and there is much evidence to indicate that such considerations are not factors of great importance.

3. It is insisted that the present program of medical education, both undergraduate and postgraduate, is of such character as to place too much emphasis on the education and training of specialists and too little emphasis on the education and training of general practitioners. It is insisted with emphasis that the postgraduate training given in most hospitals approved for the training of interns and residents is designed to satisfy the requirements of specialty boards rather than to meet the needs of general practitioners.

It is urged also that the contacts which the student has in medical school and in his postgraduate training stimulate in him an appreciation of the importance of a specialty and diminish his appreciation of the importance of the services of a general practitioner. This particular contention finds support in the results of many experiments that have been conducted for the purpose of securing more general practitioners in smaller communities. Financial aid extended to medical students on the condition that they would engage in practice in small towns or rural areas for a period of years after the completion of their education and training has not been effective to the degree expected. It seems that something happens to the ambitions and interests of such students between the time they enter the medical school and the time they complete their intern or resident training which affects an alteration in their attitudes, ambitions and outlook toward general practice.

The field of medicine is large. It has been expanded by progress. No one person can master the entire field. There is need for specialists, and there is need for a program of training which will qualify specialists. There is need also for general practitioners in even larger numbers than exist at present and there is need also for a program of education and training that will meet their needs.

It is obvious that to accomplish the distribution of physicians according to a fixed ratio to the population would not in and of itself accomplish a satisfactory distribution of medical services. Other factors are to be considered, such as the availability of the several special services which are required for complete medical care and the availability of these services as well as the services of general practitioners.

Specialization has been constructive in bringing about better medical care. It will continue to do so if kept in proper relation to the important and vital branch of general practice. It becomes destructive in its effect when the number of specialists is too large in proportion to the number of general practitioners. It was reported to me that the State Board of Medical Examiners for one state last year asked that each applicant for a license state the type of practice in which he intended to engage. The replies revealed that only 7 per cent intended to engage in general practice. There can be no doubt that a need exists for the restoration of the family physician, or general practitioner, to the position of importance and prestige which he once occupied and which he deserves to occupy today.

The painting by Sir Luke Fildes called "The Doctor" was painted by command of Queen Victoria to commemorate the devoted service of a family physician to the sick child of one of her servants.

In a recent issue of the *Saturday Evening Post* (April 12, 1947, p. 30) under the heading "Norman Rockwell Visits His Family Doctor" there appears a story which every physician and every layman in this country should read. In text and drawings the author describes and portrays something of the life and service of a general practitioner and something of the esteem in which he is held in his community. His place is still high in many communities. It is still high in the hearts of many persons, but too many such places are vacant. I dare say that there is nothing the matter with the public relations of the medical profession in any community that is served by a general practitioner of the type described by Mr. Rockwell.

It seems to me that the whole field of medical education and medical service deserves special study by a special committee of this Association. I therefore recommend that this House of Delegates take action to request the Board of Trustees to appoint and finance a special committee of whatever size is deemed necessary for the purpose of studying all the factors which affect the production and distribution of the type and quality of medical care which the people need and/or desire. In particular such a *committee could: (1) define the term "general practitioner,"* or "general physician," on a functional basis; (2) determine whether or not there is need for a large increase in the number of medical graduates and, if so, its extent; (3) study the present program of medical education and training, both undergraduate and postgraduate, to determine whether or not the content and administration of the program is properly adjusted to the present day needs of the people; (4) study the possibility and feasibility of utilizing smaller community hospitals in a program for the training of general practitioners and the possibility of approving such institutions for such training when a teaching program is properly organized and administered; (5) study the means by which communities in need of additional services may be aided; (6) study such other questions as the committee itself may determine to be necessary in arriving at sound conclusions concerning the entire field of medicine, and (7) propose a long range program designed to overcome present insufficiencies and to meet future needs.

The public relations of this Association have been affected unfavorably by conditions which exist, notwithstanding the fact that the Association is without authority to direct or influence the formation and execution of policies of medical schools and hospitals except to the extent of approving those institutions with programs and facilities which meet certain standards and of disapproving those whose programs do not. This Association does not possess, and does not seek, the power to compel a physician to render service at a place or of a type that is not congenial and satisfactory. Nor does it want any government agency to possess and exercise such powers.

I submit as my opinion that the public relations of this Association are intimately concerned with these particular problems and issues, and that the public relations of the Association will be far more favorably influenced by an effort to solve these problems, which are of such concern to the physician and to the patient, than by a public relations program per se, however expertly administered.

There are many other problems facing medicine. There always will be. There would be no challenge to genius if there were no problems. It is by the solution of problems that progress is brought about. I repeat a statement made many times by many Fellows of this Association, that the medical practitioner is qualified by education, knowledge, experience and idealism to solve these problems. The medical profession in cooperation with the people, on a voluntary basis, will solve these problems, if they are solved at all, on a basis that conforms to the highest aspirations of both groups.

In conclusion, I wish to express my complete faith in the courage, wisdom and idealism of this House of Delegates.

Address of President-Elect

The Speaker called on Dr. E. L. Bortz, *President-Elect,* who, after announcing that 125,000,000 stamps were that day being released to the American public in recognition of the distinguished services of medicine to humanity, delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

When you conferred the highest honor within your power on Dr. Olin West one year ago, it was a recognition of the distinguished service which he had rendered to organized medicine. His understanding of medical problems and the medical needs of the nation and his executive ability to carry out your mandates were repeatedly demonstrated during his long years of service. The turn of events which brought his resignation has elevated the vice president to the high position of President-Elect. I am deeply conscious of the significance of this elevation.

For many years I have been interested in medical education. It has been my privilege to be a member of the Council on Scientific Assembly which is responsible for the general meetings and also collaborates with the sections in drawing up the program for the annual session.

The superb resources of American medicine have brought medical education to its present state of efficiency. Indeed it may be emphasized that the principal aim of this Association is the maintenance of the highest possible standards of professional training for members of the medical profession, thereby to afford the best possible service to the American public.

EXTENSION OF SCIENTIFIC PROGRAM

The medical schools and special organizations, such as the American College of Physicians and American College of Surgeons, are extending their programs in particular fields. The time is appropriate for the American Medical Association to consider seriously the possibility of an additional scientific session planned for general practitioners of the nation. Such a program might be a two day general session held at the time of the semiannual meeting of the House of Delegates. Specific details could readily be arranged by the Council on Scientific Assembly in collaboration with the Section on General Practice of Medicine.

The membership of the Association and its various important activities have grown so that relatively few cities offer adequate facilities for the annual session. As time passes the size of the Association and the scope of its activities will grow still further. At the present session a large number of our members are not in attendance because of the unavailability of housing space.

Therefore may I respectfully urge that this House take up the problem of utilizing the semiannual meeting for additional scientific instruction.

A further point of merit would be a change of meeting place for the semiannual session. For example, were the nation divided into geographic districts, say eight or twelve in number, the House of Delegates at its semiannual session might convene in the New England area one year, at which time a two day scientific session for the general practitioners would be held; the following year it might elect to meet in some other areas as the Midsouth or Midwest or Far West or South. In this way a rotation of meeting places would bring the excellent resources of the Association to particular areas and furnish, at least for the membership in that particular area, opportunities for study that may not yet have been fully utilized. Collaboration with state medical societies in areas in which the meetings would be held could be readily worked out; it would seem that this scientific session might be fused with the scientific programs of the states involved. The suggestion has the merit that this development would, in a way, take off in part the pressure of the large annual session and, at the same time, extend additional instruction to a larger number of the Association members. I hope the House of Delegates will study this proposal.

AFFILIATION OF MEDICAL STUDENTS

Another point which needs study is the closer affiliation of neophytes of medicine, the third and fourth year medical students. This group should be brought into the medical family at the earliest possible time and given the privilege of more active participation in the activities and privileges of the Association. From this group will come the physicians of the future. Indifference on the part of the Association to this group may be corrected by affiliate membership, the reestablishment of a student section in THE JOURNAL and the encouragement of presentation of scientific papers at the county, state or even national level. There might even be a student section of the scientific assembly established for their benefit. Medicine should recognize its offspring—the coming generation. The benefits to be derived from bringing them into closer contact with organizational activities should develop leaders at an earlier stage in the professional careers of medical practitioners.

May I respectfully propose that the House authorize the Secretary, in collaboration with the Councils and other bureaus, to prepare an attractively illustrated booklet which will contain a description of the various activities carried on by the American Medical Association and a brief statement of the significance of these activities in behalf of the preservation of the nation's health and in support of a progressive program of medical education. In the spring of each year, or at any other time that classes are graduated from medical schools, the American Medical Association would send one of these booklets to each graduate. The young physicians of the nation would then have a guide to assist them in a clearer understanding and better appreciation of the organization that is protecting the profession which represents their life work. At present there is an utter lack of appreciation on the part of medical students and younger physicians of the vast amount of important work which is being carried on by this Association in behalf of the physicians throughout the land.

PUBLIC RELATIONS

The public relations activities of the Association need further clarification. Since its creation a century ago, the Association has been continuously active in campaigning for a better understanding of health problems and the control of disease on the part of the general population. The antagonism of charlatans, quacks and cults is evidence of the effectiveness with which the Association has waged its battle against the forces of ignorance and destruction.

Public relations is the problem of interpreting the objectives of the medical profession in terms acceptable to the public. The cooperation and support of the laity is absolutely essential in a modern program for the maintenance of health and the control of disease. Each physician has the responsibility to keep his clientele informed of the aims toward which organized medicine is working. In this respect each physician may be regarded as a public relations contact, or better still human relations contact, which the profession in general should utilize.

QUALIFIED SPOKESMEN

Organized medicine needs more experienced representatives who may appear before lay groups and legislative bodies. These spokesmen should emphasize that the energetic program of the Association is in the public interest and for the protection of all members of the population. Too frequently the general public and at times the press also receive the impression that the medical practitioner is motivated by selfish interests and indifference to the public weal. Nothing could be further from the facts. A vast amount of convincing data is available through the bureaus and councils of the American Medical Association which will demonstrate clearly that physicians are leaders in the field of social progress and in the control of disease. During the last hundred years the human life span has extended from forty years in 1847 to approximately sixty-seven years in 1947. It is impossible to mention all the epochal contributions which medical science has made and organized medicine has fostered in the interests of a more abundant life for the people of our land.

Speakers' bureaus for the training of those who are willing to serve their profession should be organized in every county medical society. Adequate material will be furnished these bureaus by their state and national organizations.

THE WOMAN'S AUXILIARY

The Woman's Auxiliary of this Association was founded twenty-five years ago, so on this happy occasion the Auxiliary is celebrating its Twenty-Fifth Anniversary. Congratulations are in order. The fair ladies are favored by nature in their understanding of social relations and in their intense loyalty to this great profession. The Auxiliary represents probably the most important instrument in the field of public relations which organized medicine has, and yet its value has been for the most part overlooked. In many ways the Woman's Auxiliary can explain to the public the ideals and objectives for which medicine stands. A word of caution to the members of the Auxiliary as to Association members: a well informed mind using statements based on factual data available from the Association files is essential before any statements are made to public groups. The members of the Woman's Auxiliary should utilize the publications of the various bureaus and should seek counsel from the headquarters staff in order that a clearer understanding may exist of the issues at stake. Armed with this information the Woman's Auxiliary may play a determining role in its contacts with women's organizations, ladies of the press, religious groups and, not least in importance, the women members of legislatures. The Woman's Auxiliary is facing a period of expanding opportunity.

THE NURSING CRISIS

Within the past few years a serious crisis has developed in the nursing field. A questionnaire issued by the American Surgical Association indicated that the quantity of nursing talent available was 60 per cent of what it should be, and the quality was estimated as down to 75 per cent. It must be admitted that the nurses have many real grievances today. While special groups in the field of public health, industrial work, teaching and administration are rapidly moving toward more stabilized hours of work, better compensation and programs for social security the status of the private duty nurse and the general floor nurse in the hospital is unsatisfactory. Long hours, irregular employment, lack of any pension or security program and indifference on the part of groups which should be cognizant of the nurses' needs has caused a serious shortage in one of the noblest of the nation's professions. It is high time that physicians study the various ramifications of these issues and exert their influence in support of the objectives which the members of the nursing profession are now striving to attain.

I hope that this House will move that the President name a committee of five, to be known as the Committee on Nursing Problems. This committee would investigate the present objectives of the nursing profession, the standards of education, the time involved for training, the various curriculums, the supply of nurses and quality of services rendered, remuneration, participation in the determination of administrative policies and the question of security benefits. This committee would further act as a liaison with the various nursing organizations and would obtain information of significance to serve as the basis of a report to the House of Delegates at its next meeting. This Association should be able to make a definite contribution in behalf of its close allies—the nurses.

ACTIVITIES OF COUNCILS AND BUREAUS

Each member of this House should be clearly informed concerning the many activities of the departments, bureaus and councils in the headquarters of the American Medical Association. In addition to the many publications issued at regular intervals, the large staff of competent investigators and their assistants is carrying on studies of the greatest importance in the field of medical education, public instruction and the distribution of physicians. Problems of public health, rural medicine, health insurance and related fields are being studied by highly qualified experts.

The accomplishments of the Council on Medical Education and Hospitals have been widely heralded. Improvements in the training of physicians and in hospital service have been brought about in many instances through the influence of this council.

The Council on Physical Medicine is conducting studies in the realm of atomic energy and the application of radioactive substances in the field of medical research; the Council on Pharmacy and Chemistry and that on Foods and Nutrition have extensive programs for the investigation of a number of products in their respective fields. The field of Industrial Health is being examined by that council so that recommendations for the improvement of conditions under which industrial employees work may be extended to industries throughout all sections of the country.

Work of the Council on Medical Service and its contributions in the field of professional relations, special studies and assignments and the programs of regional conferences have been of the greatest benefit to organized medicine. It has published a reliable directory of plans for the various forms of voluntary health insurance. Before issuing its stamp of approval each plan is carefully examined and flaws when present are pointed out. Publications from this council are available to any one who is interested in making a contribution to the problem of health insurance.

One of the most active bureaus supported by the Association is that on Legal Medicine and Legislation. Wise counsel from the director of this bureau has been an invaluable aid in evaluating the significance of the many legislative activities bearing on the practice of medicine as they appear at regular intervals in the national and state legislatures. This council has been most cooperative with the state medical societies which have required information from time to time.

Attention should be drawn to the recently created Bureau of Medical Economic Research, which is under the direction of Dr. Frank G. Dickinson, distinguished economist, who recently joined the staff. This bureau has a far reaching research program for the examination of the supply and demand problem, the distribution and cost of medical service. Many investigations are under way. The data already collected and analyzed indicate convincingly that the plan of action which the Association has followed during the past several years is in accord with the actual needs of the nation. From time to time constituent medical societies will be furnished important statistics that may be used in state and national legislatures for illuminating health problems under discussion.

MEDICAL PREPAREDNESS

The Committee on National Emergency Service has studied the data collected from some 25,000 questionnaires and letters sent in by members of the Association. These physicians for the most part have voiced their opinion of medical service in time of war and have offered suggestions which, if implemented, will lead to higher efficiency of medical service in the event of a future catastrophe. The American Medical Association will actively cooperate with governmental officials on the highest civilian level to work out a program that will, it is hoped, be formulated for prompt medical service if the need should arise.

A NEW HOME FOR THE AMERICAN MEDICAL ASSOCIATION

The rapid expansion of activities in the various fields of medical education and the promotion of health programs for the nation has necessitated a decided increase in personnel and equipment at the headquarters of the American Medical Association. Already the present home of the Association is bulging at the seams and space is at a premium. During the next twenty-five years even greater activity with some increase in personnel will be necessary.

The House of Delegates must take under advisement a building program. Adequate time should be taken to study the medical needs of the nation as they will appear in future years. With this in mind a structure should be raised, a cathedral of health, if you will, dedicated to the high service of health maintenance, the prevention of disease and the extension and enrichment of human life. The American Medical Association has never been as powerful and influential as it stands today. From all quarters of the land its counsel is sought, its recommendations asked for and its approval desired. It is moving in forward directions. The American Medical Association is on the march to more and greater accomplishments. The time is appropriate for the House of Delegates to survey its present status and draw up adequate plans for the future.

On motion of Dr. E. S. Hamilton, Illinois, seconded by several and carried, the House recessed at 12:30 p. m. to reconvene at 2 p. m.

Monday Afternoon, June 9

The House of Delegates was called to order at 2:10 p. m. by the Speaker, Dr. R. W. Fouts.

Reports of Officers

REPORT OF SECRETARY

The Secretary, Dr. George F. Lull, presented his report as printed in the Handbook of the House of Delegates, requesting the delegates from the constituent associations personally to introduce the resolutions contained in his report. The Speaker referred the report of the Secretary to the Reference Committee on Reports of Board of Trustees and Secretary.

On motion of Dr. L. J. Kosminsky, Arkansas, duly seconded and carried, consent was given unanimously to interrupt the regular proceedings of business to introduce some foreign guests.

Addresses of Major General Raymond W. Bliss and Rear Admiral Clifford A. Swanson

Dr. E. L. Henderson, Trustee, introduced Major Gen. Raymond W. Bliss, Surgeon General of the United States Army, who presented the following address:

As an humble member of the medical profession it is a great privilege to be here in Atlantic City this week. It is intensely stimulating to be associated with my colleagues and in listening with them to the expositions and discussions by the leaders in medicine on the current thoughts in medical knowledge.

I am honored to speak to you as the representative of army medicine. What is the status of army medicine and where is it headed?

Army medicine, the Army Medical Department, is at this time in one of the critical periods of its existence. The current and prospective mission of the Medical Department is many times greater than it was prior to World War II. However, the means of the Medical Department to accomplish this mission have not increased but have actually diminished. Because of many reasons we are wofully short of the small nucleus of doctors necessary for our regular corps. We must, first of all, rebuild our regular Army Medical Corps. I believe that the plans being carried to completion toward this end are founded on a professionally sound and solid basis. They are being developed with the accepted advice from and complete cooperation with the leaders in civilian practice.

One of these ways to this desired objective is the bill now before Congress about which I am sure the Secretary of War, Mr. Patterson, will speak to you. I cannot endorse this legislation too strongly. I consider its passage essential.

There is under consideration unification of the armed services. Whatever the outcome of that, we must certainly have a unification of effort by full cooperation and by every coordination in the use of the respective means of all the government medical services, Army, Navy and Public Health and the Veterans Administration, in intimate conjunction with the means of the best in civilian medicine, if we are all to function in the most effective manner.

We must, of course, draw on civilian resources. Fortunately these resources are available. It is our responsibility to make full use of them.

In the Army we have made a beginning this past year to do, with the help of civilians, what we could not possibly have done alone—to keep the quality of our professional care as high as possible—to develop a residency training program so that the army doctor could grow professionally—to supervise and keep under constant appraisal the work of all our medical installations, and by our study and research keep part of an eye toward the future. We have started; we will continue.

In the past, the Army Medical Department has made significant contributions to the progress of medicine—witness the names and work of Beaumont, Reed, Sternberg, Gorgas. We have every reason to expect that it will make similar contributions in the future. But to accomplish this and to discharge its responsibility to the Army, the Medical Department must become part of the major stream of American medicine. That is where the Medical Department is headed.

Dr. Henderson then introduced Rear Admiral Clifford A. Swanson, who addressed the House as follows:

First, I want to offer the Navy's acclaim and congratulations to the American Medical Association, which has just attained its one hundredth anniversary. To have become a centenarian is a much greater distinction for an institution than for a man. A man might attain that age without justification—so far as his neighbors and associates can see—but an institution—at least in America—can survive and grow only because the people want it. The American Medical Association has held its strength and vitality through all the economic and social changes of the last hundred years because it has upheld the standards of medical practice and medical education. Through its leadership and its many publications it has sustained a plane of medical practice which both the profession and the population at large will continue to demand and which they know they can be assured of only by the continued strength of the American Medical Association.

Among the many problems that confront the Medical Department of the Navy today there are several in which the general medical profession has a distinct interest; there are some that must be shared and faced mutually by, and in their solution, with mutual benefit to, the civilian profession and the Navy Medical Corps.

One of the first and most serious of these is the matter of atomic weapons, particularly defense against them and the medical features of this defense.

About a half century ago, when the American Medical Association was only a half century old, the work of Roentgen, Becquerel and the Curies in radioactivity and then the epochal pronouncement of Einstein that matter can be transformed into energy to the tune of his fundamental law that $E = MC^2$ started us on a long march that reached a world shaking climax at Hiroshima and Nagasaki two years ago. Until those fateful days in August 1945 the world and the medical profession at large knew nothing of the medical implications of an atomic explosion because, until then, none but those of the inner circles of atomic bomb production knew that there was even such a thing as an atomic bomb. Since then, however, knowledge of the biologic effects of atomic weapons has rapidly accumulated and has been widely disseminated. There is now in progress in the two Japanese cities a survey of biologic effects which may continue for years in order to give us the long range picture. Much more closely controlled studies have been possible with the Bikini animals, and this work may also continue for some years at the Naval Medical Research Institute.

As every one is now well aware, civilian casualties in atomic warfare can reach huge proportions and will be of a clinical pattern that was little known before 1945. Problems of evacuation, of treatment, and the great public health problem of radioactive contamination of large areas of human habitation as demonstrated by the underwater explosion at Bikini are matters that cry for answers and extensive planning, both by military and by civilian medical authorities.

There are unprecedented industrial hazards in the manufacture and handling of fissionable materials. The safety records established by those responsible for safety precautions and regulations in the manufacture of the bombs, and during the explosions in the presence of some forty thousand people at Bikini, are really phenomenal; in fact, those safety records were perfect. They show the possibility of achieving an incredible degree of safety even when surrounded with hazards of unimaginable potentialities, As the scale and intricacy of manufacture are increased and as the uses of fissionable materials are multiplied there will be larger industrial medical tasks to perform in devising safety measures and in the constant education of personnel as to the observance of the precautions that must be established.

But even, we are happy to say, such an ill and terrifying wind as a war has blown some good. There is indeed little, if anything, good that can come out of a war, but of one thing we can be sure—it always furnishes a tremendous impetus to scientific advances. And one great by-product has come to us in a whole new array of radioactive isotopes that may prove to be of high clinical value. This is a field whose exploration by medical research workers is still in the pioneer stage but which may open up a new medical world of fruitful returns. In the Navy this work is being directed by the newly formed Division of Atomic Defense in the Bureau of Medicine and Surgery.

The Navy is always working on plans to meet possible future disasters. In caring for civilian casualties in future wars there may be many occasions when the situation will call for the combined and coordinated efforts of civilian and military medical personnel. As an illustration in this connection it is of interest that in the recent disaster at Texas City, Texas, which attracted national attention, the lives of a considerable group in the rescue party were probably saved because a medical officer promptly evacuated the injured and medical personnel from the first aid station, which shortly afterward was engulfed by the flames of an exploding oil tank. This officer's war experience probably assisted him in making the decision, as he was a veteran of the Pacific campaign.

One of our most acute and pressing problems in the Navy today is that of obtaining and of holding medical officers. Having witnessed the general shortage of doctors and nurses and the consequent understaffing of civilian hospitals in recent years, you will understand what it means to have to spread thinner and thinner the medical personnel that is required to carry on a heavy medical program. You will understand too some of the reasons for our present shortage in the Navy. Medical education has become a long and expensive process. Consequently, the medical officer in the Navy begins his career considerably older—and poorer—than officers of similar rank in other branches of the Navy. He has already spent more money on and devoted more years to his education than one does in any other profession. To correct this situation we have designed some legislation which is now in Congress and which, of course, we hope will receive favorable action there. It provides for a substantial increase in compensation and thus, if passed by Congress, will offer a much needed incentive for young medical men to consider entering the Medical Corps of the Navy as a career. But we must offer them, and we are offering them something as vital, as financial incentive, and that is the opportunity for professional advancement. We are offering internships and residency training in our naval hospitals; training which meets the approval of the A. M. A. Council on Medical Education and, for purposes of credit toward certification by the various specialty boards, residency training in a number of medical and surgical specialties, including obstetrics and gynecology, of a quality and scope that is approved by those boards. Also we are now carrying out a program of unprecedented size in sending medical officers to extensive postgraduate courses at various of the great universities and medical centers of this country.

I should like at this point to touch on the problem of unification of the medical services of the armed forces. Both General Kirk and I have appeared before committees of the Congress in support of the National Security Act of 1947, commonly known as "the Armed Forces Unification Bill." I am sure we are in close agreement as to the principle of attaining several desirable objectives which we feel are most worthy as far as the medical services are concerned.

I believe these objectives to be:

(*a*) To provide the best possible medical services for the armed forces with the total means available.

(*b*) The most efficient utilization of Medical Department personnel—physicians, dentists, nurses and other assisting personnel—in order best to carry out the overall mission of providing the medical services required for the armed forces in peace and war.

(*c*) The realization of all possible economies in the use of funds, facilities, installations and personnel which are compatible with acceptable and modern standards of medical services for the armed forces.

(*d*) The balancing of the medical needs of the armed forces in relation to the total medical resources of the country.

(*e*) To promote and maintain the highest possible professional caliber of the medical personnel of the national defense establishment.

(*f*) To insure that the medical aspects and the medical implications of any future war are taken into full consideration at all policy-forming levels and at all stages of planning in the national defense structure.

It seems to me that the chief difference between the plan which was proposed by General Kirk and my concept lies only in the organization methods by which we propose to accomplish these objectives. When all the realities and ramifications of the problem are taken into consideration, I believe that the most workable method of bringing about the desirable ends I have just enumerated is by working through the agencies which are provided for in the proposed National Security Act. As a logical part of their functions as prescribed in the bill, these agencies, i. e. the Joint Staff, the Munitions Board and the Research and Development Board, under the direction of the President and the Secretary of National Defense, would be expected to discharge the responsibility of establishing a pattern of close team work between the medical services of the armed forces, just as they would perform similar functions in respect to the other fields of military endeavor. I believe it is only reasonable to expect that each of these agencies in its own sphere would want and would have a medical subboard or medical committee, which I have chosen to call a "medical component," to assist and advise it in all medical matters and in all problems having substantial medical implications. I believe the medical components of the three agencies to which I have just referred should each be composed of the Surgeons General of the respective branches of the armed forces, or their appropriate deputy medical representatives, together with a civilian medical representative where appropriate.

At the higher level I have advocated that there also be a medical component to assist and advise the National Security Resources Board in the medical aspects of that board's prescribed function to advise the President concerning the coordination of military, industrial and civilian mobilization; further, that this latter medical component or council at the national level should be composed chiefly of representatives of the civilian medical profession at large, with a minority of associated military medical representatives.

I sincerely believe that the acceptance of such a concept as I have outlined will not only insure medical participation in military planning and in the determination of national defense policy at all levels but will also be a long step forward in recognition of the great importance which medical matters must henceforth be accorded in providing for the national security in time of critical national emergency.

It should be of interest to the entire medical profession to know that the Secretary of the Navy and the Navy Department have sanctioned and concurred in my concept of the overall medical plan which I envisage would be brought into being as a natural consequence of the enactment of the National Security Act of 1947.

What might be called the overgrowth of specialism in medicine has posed another serious problem to the Medical Corps of the Navy. The Navy has many specialists in all fields of medicine and surgery and we realize that they are all needed, but the naval surgeon must always be a good general practitioner who can face the ordinary emergencies of medical practice fully equipped to deal with them. The Navy after all is a seagoing organization, and a considerable number of our naval doctors must be with the forces afloat or at overseas stations. A large ship such as a battleship or carrier may easily have from 1,500 to 2,500 officers and men on board. Two or three doctors to form a medical staff must deal with most of the problems that a physician is expected to need in a community of that size. If they are in the middle of the Pacific and a surgical emergency arises, they cannot send the patient around the corner to a surgeon. True enough, these patients at a later date may be transferred to a hospital where specialists of every sort are on hand. But a great deal of active medical and surgical practice must be carried on directly by the medical man on the ship. We need, as you see, to have many well trained and capable general practitioners.

From three to five years of general practice has always been regarded as a sound basis on which to begin specialization. It has been said that the average general practitioner in civil life is a specialist in obstetrics. The average naval surgeon we like to think of as a general practitioner who is a specialist in traumatic surgery and preventive medicine. Many of our leading specialists in the Medical Corps have come through this preliminary training in the field of general practice, and we feel that they are better specialists for it and certainly they are better medical officers. It is surprising how well a radiologist can take out an appendix or an ophthalmologist can take care of a pneumonia patient when a general surgeon or an internist is not available.

But now the trend seems to be that the newly graduated doctor, as soon as he has completed his internship, feels he must enter immediately on his residency training for specialization. As a medical man I believe this is wrong.

This tendency, it appears, has been fostered in considerable degree by the growing influence of the specialists' boards. Now the one consuming aim of the young doctor, from the time he graduates from medical school, is to rush toward the day when some specialist board will certify him. Everything else—so it seems—such as the matter of becoming a good and useful practitioner in his community (or in one of the government medical services) fades to a level of secondary importance.

There is no doubt that the specialist boards have rendered a great service to medicine. Doubtless they have done much to raise the standards of medical education and specialist practice. But if the boards have the effect of driving every medical graduate into some specialty they are doing the profession and the citizenry a disservice. We are suffering from this specialism stampede in the Navy and I suppose that civilian practice is similarly feeling it effects.

And I should like to leave with you this parting thought: that we might well take stock of this situation and return to the more conservative formula of superimposing specialty training on a broader foundation of general clinical knowledge.

Reports of Officers

REPORT OF BOARD OF TRUSTEES

Dr. R. L. Sensenich, Chairman, presented the Report of the Board of Trustees as printed in the Handbook, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of the Report of the Committee on National Emergency Medical Service, which was referred to the Reference Committee on Emergency Medical Service.

SUPPLEMENTARY REPORT OF BOARD OF TRUSTEES

Dr. Sensenich announced that the Board would submit a supplementary report in executive session and then submitted the following supplementary report, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

Mr. Raymond Rich and Mr. Swart have resigned, and the Board has accepted their resignations as immediately effective. The Board of Trustees in 1946 employed Raymond Rich Associates to make a survey of the activities of the American Medical Association. This survey was reported to the House of Delegates at the session in San Francisco in July and at the same time the Board indicated actions already taken to make effective some of the recommendations. At the December session a further consideration was given to the entire report, and the House of Delegates made certain specific recommendations. In the meantime, the Board of Trustees has been concerned with the budgets and the expansion of the activities of various departments, councils and bureaus, including the Division of Public Relations. During the past six months most of the activities of the Division of Public Relations have been concerned with the centennial of the Association. Mr. Raymond Rich was employed as a consultant for this period. The Board of Trustees has authorized the General Manager to conduct further investigations as to the next steps in the public relations activities of the Association. The Board proposes to arrange for suitable public relations counsel. When the activities in connection with the Centennial come to an end, a redistribution of present personnel may be feasible, an increase of personnel will be made where necessary and additional funds will be made available. These facts will permit more intensive promotion of the public relations of the Association with reference to its national health program. For the remainder of the present session, Mr. John Bach will be in charge of the Press Room, and the General Manager and the Editor will advise on questions related to the House of Delegates and the scientific program respectively.

REPORT OF JUDICIAL COUNCIL

Dr. Edward R. Cunniffe, Chairman, presented the Report of the Judicial Council as published in the Handbook, which was referred to the Reference Committee on Legislation and Public Relations.

SUPPLEMENTARY REPORT OF JUDICIAL COUNCIL

Dr. Cunniffe presented the following supplementary report of the Judicial Council, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

This report pertains to the resolution adopted at the meeting of the House of Delegates in San Francisco in July 1946, providing for a revision of the Principles of Medical Ethics, which was referred to the Judicial Council.

The Principles of Medical Ethics were first written for the physicians of England in 1803 by Dr. Percival, and in 1847 at the meeting of the American Medical Association held in Philadelphia Dr. Isaac Hays was appointed chairman of a committee which was instructed to formulate Principles of Medical Ethics for the American Medical Association. Dr. Hays reported the consummation of this assignment at the meeting of the American Medical Association the following year. In the presentation of this document he followed very closely the Principles of Medical Ethics as laid down by Percival some sixty years earlier.

These Principles were modified somewhat in 1880 and since then a few additions have been made to them. But with very little change in their context, they have served the American Medical Association for practically one hundred years. Modifications and additions have been written in the language of several different periods, and the Council feels that this language should be rewritten so that it may be more easily interpreted.

However, we must weigh carefully each change in the structure of this revision on account of its great importance in relation to the conduct of members of the medical profession.

Under the old, but slightly modified, Principles of Medical Ethics adopted in 1848 the medical profession has progressed, has attained its present high position and has been responsible for great scientific achievement. The Council will not recommend changes in these Principles without the careful study and the mature deliberation which the problem merits. It is a work which must proceed with great caution. As Winston Churchill has said, "It has been my experience in great affairs that none of the fine accomplishments have ever been made other than slowly."

Realizing the importance of this matter, the Council at different times has requested those who introduced the resolution and any others who wished to offer suggestions to communicate with it and has offered the assurance that these communications would be gratefully received. Despite these appeals, only three letters have been received. In two, it was suggested that the Principles of Medical Ethics remain as they are, and in the third the Council was requested to provide laws or codes instead of principles to govern the conduct and activities of physicians.

The Council desires to make a sound revision which will not only have permanent value but will provide for adjustments which will fit changing conditions. There are many important factors involved in the consideration of this problem, and the Council again appeals to all those who are interested to send to it suggestions which are considered to possess value. These suggestions will receive serious consideration. Particularly will the Council appreciate suggestions concerning principles rather than laws or codes.

The Council is now studying that phase of the Principles of Medical Ethics which pertains to those high ideals which should motivate the conduct of the physician in relation to his patients and in relation to other physicians rather than that phase which deals with economics or ethics. It does not believe that a sound revision of the Principles of Medical Ethics of enduring value can be made hurriedly.

The Council feels that a more specific or detailed report should not be made until its task is nearer completion, and this statement is offered as a progress report only. It is submitted with the suggestion that the approval of the House of Delegates be granted for a continuance of this important study by the Council.

Respectfully submitted,

EDWARD R. CUNNIFFE, Chairman.
LLOYD NOLAND.
JOHN H. O'SHEA.
LOUIS A. BUIE.
WALTER F. DONALDSON.

REPORT OF COMMITTEE ON CENTENNIAL CELEBRATION

Dr. Edward R. Cunniffe, Chairman, presented the following report concerning the program for this Centennial Celebration:

I am sure that you are all aware that a commemorative stamp has been granted by the government, which was issued today and is at hand and available at a desk in the lobby of this hotel. I should like to call your attention to the fact that 125,000,000 of these stamps have been printed, that 80,000,000 stamps have been ordered by the various postmasters in the United States, and that there are 2,000,000 stamps in Atlantic City today.

It is customary when a commemorative stamp is issued that a certain ceremony be followed, and that will happen tonight at the dinner of the House of Delegates, when Assistant Postmaster General Lawler will be presented to the House and will make a short address in presenting an album with the stamps to Dr. Shoulders, your President, who will respond in behalf of the Association. This will not take very long. It will be a very short ceremony.

The stamp, of course, is a painting of an old picture called "The Doctor." I don't know who ordered the painting, but the physician who is shown in this painting was a physician to Queen Victoria and also to King Leopold of Belgium. We will have the original working drawing of this painting on exhibition sometime during the week. It is the property of Dr. Donald Guthrie of Sayre, Pa., and he has sent it down with a description of the events that concern the painting. The painter wanted to show the physician, not as a physician to royalty, but rather as one to the poor, and that is the reason it has been selected for this stamp.

The program continues tomorrow night with a general meeting, and that meeting will open with a musical program, to be followed by an invocation to be given by Rev. Mortimer Sullivan. Then announcements, if necessary, will be made by the chairman of the local committee and the chairman of the Centennial Committee. Following that, the chairman of the Centennial Committee will introduce foreign guests. The installation of the President will follow, after which there will be a presentation of the Distinguished Service Medal by Dr. Bortz, followed by the introduction of more foreign guests by the President.

Dr. Sensenich, Chairman of the Board of Trustees, will then present the President's Medal to the retiring President, Dr. Shoulders, and also make the awards of Honorary Fellowships to foreign guests.

I forgot to say that Dr. Bortz will present the Distinguished Service Medal to Dr. Christian.

On Thursday night the President's Ball will be held in Convention Hall, Wednesday night being given over to the fraternities and societies for their meetings and dinners. At the President's Ball music will be furnished by two famous orchestras providing dance music. There will be three reception lines, one headed by Dr. and Mrs. Shoulders, Dr. David B. Allman, chairman of the local committee, Mrs. Allman and ten foreign guests; the second line, by Dr. and Mrs. Bortz, Dr.Hilton S. Read, the deputy chairman of the local committee, and Mrs. Read and ten foreign guests; and the third line, the President-Elect and his wife, if he is not a bachelor, Dr. Royal Schaaf, president of the Medical Society of New Jersey, and Mrs. Schaaf and ten more foreign guests.

I think I would be remiss if I did not say a word about the fact that "The History of the American Medical Association" is now ready and on sale. It is very well worth while, and I am sure the men will take a great interest in securing copies and taking them home with them.

I also want to say at this time, because I probably will not have a chance to come before you again, that the committee has worked hard in formulating this program, with the exception of the chairman. I have just the honor to report their hard work to you, because it has been very easy for me. I must say that, without the help of Dr. Fishbein, Dr. Lull and Miss Niehoff, this could not have been accomplished. There have already been two days of this program, the dinner on Saturday night and the services yesterday morning, which I think have been fairly successful. I want to say that we appreciate very much the work which they have done, and without them we could not have done anything. Thank you very much.

REPORT AND SUPPLEMENTARY REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

Dr. Edward L. Bortz, Chairman, presented the report of the Council on Scientific Assembly as published in the Handbook and the following supplementary report:

REQUEST FOR SECTION ON PHYSICAL MEDICINE

The Council on Scientific Assembly has received a request from the Council on Physical Medicine for the establishment of a Section on Physical Medicine.

RESOLUTION ON CONFERRING HONORARY FELLOWSHIPS

Resolved, That the House of Delegates authorize the Board of Trustees to confer Honorary Fellowships on (*a*) those distinguished guests in attendance at this session who are official representatives of foreign governments, (*b*) official representatives of foreign medical associations and (*c*) all distinguished guests who have been invited to present papers before the General Scientific Meetings and the sections of the Scientific Assembly.

Dr. Bortz reported that action on the resolution would be needed at once if it is the will of the House to confer Honorary Fellowships on the distinguished foreign guests.

It was moved by Dr. L. G. Christian, Michigan, and seconded by Dr. Thomas S. Cullen, Maryland, that the House resolve itself into the Committee of the Whole. The motion was lost on a rising vote.

Dr. James R. Reuling, New York, moved that the usual order of business be suspended and action on this resolution be taken at this time, and the motion was seconded by Dr. Mather Pfeiffenberger, Illinois. After discussion, Dr. Reuling withdrew the motion and substituted another motion, with the intention of a twenty-four hour notice, to elect the invited foreign guests Honorary Fellows at the meeting the next day and the substitute motion was seconded by Dr. Thomas S. Cullen, Maryland.

The Vice Speaker, Dr. F. F. Borzell, suggested that with the presentation of the following proposed amendment to the By-Laws and its adoption the next day the question would be answered:

Amend the section of the By-Laws referring to Honorary Fellows to read:

"Honorary Fellows: Physicians of foreign countries who have risen to preeminence in the profession of medicine and who are in attendance at the session may be elected to Honorary Fellowship by the House of Delegates on the nomination of the Council on Scientific Assembly. The several sections may make recommendations to the Council on Scientific Assembly regarding individuals for such nomination.

Dr. Holman Taylor, Texas, moved to amend the motion by suggesting that the revised By-Law quoted by Dr. Borzell as a part of the proposed revised Constitution and By-Laws be voted on before the suggested revision of the entire Constitution and By-Laws is considered. The suggested amendment of Dr. Taylor was seconded and carried, after which the Speaker declared that amendment before the House for action the next day on the Report of the Reference Committee on Amendments to the Constitution and By-Laws.

PROGRESS REPORT OF COMMITTEE ON NATIONAL EMERGENCY MEDICAL SERVICE

Dr. E. L. Bortz, Chairman, presented the report of the Committee on National Emergency Medical Service as printed in the Handbook, including the revised part of the report as follows, which was referred to the Reference Committee on Emergency Medical Service:

Revised Portion of Report of the Committee on National Emergency Medical Service

On the basis of studies of questionnaires returned and of letters from key individuals, and after eliciting the considered opinions of representatives of the Army, Navy, United States Public Health Service, the Veterans Administration, Federal Security Agency, the Secretary of the Interior and the Advisory Medical Committee to the Secretary of War, and after a thoughtful review of the events of medical participation in World War II, and in consideration of the current developments in modes of warfare, the Committee at this time desires to present to the Board of Trustees for transmission to the House of Delegates the following recommendations:

I. That the President of the United States of America and the Congress be respectfully urged:

(*a*) That in war and in peace the Surgeons General of the armed forces have the authority and responsibility for participation, with commensurate rank and at the level of the chiefs of staff and the chiefs of naval operations of the armed forces, in all military and naval planning, organization and operations as these relate to medical, health, sanitary and welfare services; and for the assignment and utilization of medical and allied personnel at home and abroad.

(*b*) To require that the Secretary of War and the Secretary of the Navy and such other cabinet officers as may be charged with responsibility for our national defense give consideration to possible civilian requirements in a total war in the planning, location and construction of military hospitals, and that they reexamine their organizational tables and other procedures used during World War II in order to avoid (1) the medical overstaffing of units; (2) the wasting of the time of doctors of medicine in the performance of nonprofessional duties; (3) the removal of an excessive number of doctors of medicine from civilian hospitals and from civilian practice; and (4) a rather widespread failure to make assignments, determine rank and provide for the rotation of doctors of medicine on the basis of their professional qualifications, experience and age.

II. That the American Medical Association go on record as favoring the creation of a National Emergency Medical Service Administration as a continuing function of government, such administration to consist of representatives of the Advisory

Board for Medical Specialties, American College of Physicians, American College of Surgeons, American Dental Association, American Hospital Association, the Catholic Hospital Association, American Medical Association, American Nurses Association, American Public Health Association, American Veterinary Medical Association and Association of American Medical Colleges.

The Administration *shall* be charged with the responsibility at all times (1) for effecting plans for total mobilization of the medical and allied resources of the nation; (2) for the procurement and allotment of medical and allied personnel in case of a national emergency; (3) for the coordination of civil and military medical and allied services in times of threatened or actual national emergency, provided that in the exercise of this function there shall be added to the administration the following members:

The Surgeon General, U. S. Army.
The Surgeon General, U. S. Navy.
The Surgeon General, U. S. Public Health Service.
The Air Surgeon.
The Medical Director, Veterans Administration.
A representative of the National Research Council.
A representative of the American Red Cross.

III. The experience of the American medical profession in the armed forces during the recent conflict and an examination of the effect of total war on civilian populations require that we participate in continuous study, planning and supervision of the adequacy of medical, health and sanitary services for the civilian population during emergencies, and the adequacy of medical, health and sanitary services in the armed forces. The survival of the United States can hinge on this action. Scientific knowledge has accelerated warfare to the point that a nation cannot wait until disaster is approaching to prepare for such horrible events. The responsibility, therefore, demands that the American Medical Association establish forthwith a permanent and authoritative body to deal with this problem.

The Committee recommends that the Board of Trustees of the American Medical Association be authorized by the House of Delegates to create and appoint a standing committee to be designated as the Council on National Emergency Medical Service.

IV. Finally, it is recommended that the present Committee on National Emergency Medical Service be discharged.

Respectfully submitted,

Edward L. Bortz, Chairman.
Harold S. Diehl.
Perrin H. Long.
Harold C. Lueth.
O. O. Miller.
James C. Sargent.
V. C. Tisdal.

REPORT OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Dr. H. G. Weiskotten, Chairman, presented the report of the Council on Medical Education and Hospitals as printed in the Handbook, which was referred to the Reference Committee on Medical Education.

SUPPLEMENTARY REPORT OF COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Dr. H. G. Weiskotten, Chairman, also presented the following supplementary report, the first section of which was referred to the Reference Committee on General Medical Practice and the rest of the report to the Reference Committee on Medical Education:

I. Upholding Prestige of General Practitioners

Considerable thought has been given to devise ways of upholding the prestige of general practitioners so that they may be encouraged to provide the citizens of our country with the kind of medical care which they are peculiarly qualified to furnish and for which there promises to be continued need.

The establishment of a Section on the General Practice of Medicine by this House in 1945 was an important step forward. Interest in this section was at once apparent, as shown by a registration of 939 at the 1946 Scientific Assembly and by the attendance of these registrants at the various meetings. This House has also expressed its approval of the organization of sections on general practice in state and county medical societies.

In spite of this, certain hospitals have inaugurated as a matter of policy limitation of their staff appointments to physicians certified by specialty boards or holding membership in certain special medical societies. Such a policy is contrary to the principles of the Council and seems unsound. In publications which have dealt with hospital standards, the Council has expressed repeatedly the need for a hospital staff of high quality; it has never mentioned certification by a specialty board or membership in a special medical society as an important credential.

Certain institutions have assured for themselves the inclusion on their staffs of properly qualified general practitioners by the intramural establishment of "General Practice Sections." An excellent description of how such a section actually operated over a period of eight years in a 450 bed hospital appeared on pages 15 through 16 of the May 3, 1947 issue of The Journal. Reprints of this article will be distributed by the Council to every registered hospital in the United States.

On the whole, so much uncertainty appeared to exist in the minds of many boards of trustees of hospitals about the propriety of establishing such sections as to lead this House at its meeting in San Francisco a year ago to adopt a significant resolution. This was reported favorably by the Reference Committee on Medical Education and adopted by the House; part of this resolution is quoted:

> Whereas, Many hospitals have not established general practice sections in their visiting active staffs, and their governing heads are doubtful whether such action has the approval of the bodies which set up the rules and regulations for the approval of their hospitals for interns and residents; therefore be it
>
> *Resolved*, That hospitals should be encouraged to establish general practitioner services. Appointments to a general practice section shall be made by the hospital authorities on the merits and training of the physician. Such a general practice section shall not per se prevent approval of a hospital for the training of interns and for residencies. The criterion of whether a physician may be a member of a hospital staff should not be dependent on certification by the various specialty boards or membership in special societies.

Copies of this resolution have been sent to the American College of Surgeons, the American College of Physicians, the American Hospital Association, the Protestant Hospital Association, the Catholic Hospital Association and to each hospital registered by the Council.

To carry forward further the intent of the resolution, the following report was published by the Council in The Journal, page 95, in the May 3, 1947 issue:

"At the direction of the House of Delegates of the American Medical Association some years ago, the Council on Medical Education and Hospitals formulated standards for the establishment of American boards for the certification of specialists and for the conduct of hospital residencies providing training in the various special fields of medicine. The aim was to improve the quality of training at this level of medical education. The physician responsible for directing such hospital training should himself have had training and experience approximately equivalent to that required of certification applicants, whether or not he is actually certified. But it was never intended that staff appointments in hospitals generally, or even in hospitals approved for residencies, should be limited to board certified physicians, as is now the policy in some hospitals. Such policies, if practiced extensively, are detrimental to the health of the people and therefore to American medicine. Hospital staff appointments should depend on the qualifications of physicians to render proper care to hospitalized patients as judged by the professional staff of the hospital and not on certification or special society memberships.

"In this opinion the Council has the full concurrence of the Advisory Board for Medical Specialties, which represents all of the American Boards in the specialties. At the February 1947 meetings of the Advisory Board it was unanimously voted to adopt as the sentiment and policy of the Advisory Board the recent resolution passed by the American Board of Surgery, which reads:

> "'The American Board of Surgery is not concerned with measures that might gain special privileges or recognition for its certificants in the practice of surgery. It is neither the intent nor has it been the purpose of the Board of Surgery to define requirements for membership on the staffs of hospitals. The prime object of the Board is to pass judgment on the education and training of broadly competent and responsible surgeons—not who shall or shall not perform surgical operations. The Board specifically disclaims interest in or recognition of differential emoluments that may be based on certification.'

"Since February, several separate American boards in the various specialties have taken similar action. The Council on Medical Education and Hospitals of the American Medical Association is completely in accord with this principle."

The Council now asks authority to use still another lever to carry forward the intent of the resolution. It recommends that section 3, paragraph 6, of the "Essentials of a Registered Hospital" now reading "6. Staff sections, such as medicine, obstetrics and surgery, should be organized as may seem wise" be amended to read "6. Staff sections, such as medicine, obstetrics, surgery, general practice, etc., should be organized as may seem wise."

This amendment is proposed in the belief that even so small a change in wording of the Essentials may be of help in promoting the intent of the resolution adopted by this House a year ago.

The desirability of doing this is plain. The establishment of an American Board of General Practice is being discussed by the Section on the General Practice of Medicine, by the Council and by the Advisory Board for Medical Specialties. The wisdom of establishing such a specialty board at this particular time is debatable. Wider realization and greater use of the contributions which skilful general practitioners can bring to hospitals may make superfluous the need for their certification by a specialty board.

Mimeographed copies of this report are available for every member of the House.

II. Revision of Essentials of Approved Residencies and Fellowships

This document, which sets forth the regulations applying to hospitals offering advanced training to physicians, was originally approved by the House in 1928. Periodically, it has been revised. The present revision brings the document up to date. It is forty-three pages in length and would require an hour and a half to read.

In the light of discussions yesterday at the "Grass Roots" conference, the House would be interested in the following statement in the Revised Essentials regarding the staff of a residency hospital:

"There should be an organized staff of ethical, licensed physicians holding the degree of doctor of medicine from approved medical schools acceptable to the Council on Medical Education and Hospitals. The particular specialties in which residents are being trained should be represented on the staff by well qualified, experienced and proficient physicians, *whether or not they may be certified in a specialty or hold membership in special societies.*"

REPORT AND SUPPLEMENTARY REPORT OF COUNCIL ON MEDICAL SERVICE

Dr. E. J. McCormick, Chairman, presented the Report of the Council on Medical Service as printed in the Handbook, which was referred to the Reference Committee on Miscellaneous Business, except the portion relating to legislative matters, which was referred to the Reference Committee on Legislation and Public Relations.

Dr. McCormick also presented the following supplementary report of the Council, which was referred to the Reference Committee on Miscellaneous Business:

Important developments in the field of medical service have taken place since the completion of the Council's annual report. Several of these are of such moment as to require additional comment at this time.

United Mine Workers Health and Hospital Fund

In the annual report the Council gave a short résumé of the situation to date, made mention of the Boone survey and outlined briefly a possible plan of action.

Specific recommendations were withheld pending the release of the Coal Mines Administration's (Boone) survey. This survey and its findings have now been made public in a three hundred page report entitled "A Medical Survey of the Bituminous-Coal Industry." To provide the delegates with a summary of the survey, the Councils on Medical Service, Industrial Health and Medical Education and Hospitals have prepared a 6,000 word résumé of the principal points and the recommendations. This résumé appears in the June 7 issue of The Journal, copies of which are available to each delegate. While the résumé does not do justice to the excellence, the scope and the objectivity of the survey, it does present the highlights and conclusions in a form sufficiently condensed so as to enable every delegate to become acquainted with the survey.

The Council recommends to the House of Delegates:

1. That a statement be prepared congratulating Rear Admiral Joel T. Boone and his survey teams on the survey, its objective approach, its scope, and its unbiased conclusions and recommendations. (Copies to be sent to the Secretary of the Interior and the Coal Mines Administrator.)

2. That a statement be prepared for the United Mine Workers Union and the bituminous coal operators' associations noting their assistance to and cooperation with the survey teams; calling attention to the fact that here is an opportunity for labor, management and medicine to work together on a positive approach to the solution of the health problems of a specific segment of the population; pointing out the plan mentioned in the Council's annual report, and requesting that formal conferences be held with representatives of the American Medical Association (Councils on Medical Service, Industrial Health and Medical Education and Hospitals).

3. That other interested groups, such as the Association of Coal Mine Physicians, American Hospital Association, American Dental Association and American Nurses Association, be called together to discuss possible approaches to the health problems of the miners and to act jointly with the American Medical Association in conferences with both the mine workers' unions and the mine operators.

Veterans Administration Home Town Medical Care Program

Undoubtedly most of the delegates are aware of the Veterans Administration Home Town Medical Care Program. Under this program the veterans were to receive medical care for service connected disabilities from physicians of their own choice, physicians were to serve for fees agreed on through their state medical societies, and every effort was to be made to provide the veterans with the same medical care received by civilians. Up to the present time some thirty-eight state medical societies have worked out agreements with the Veterans Administration for the purpose of providing the veteran with the same care he would receive as a private patient. To this decentralized, free choice program the Veterans Administration agreed.

There are now indications that new factors have arisen that have resulted in the Veterans Administration altering its policy. It would seem now that its policy is to set up more and more clinics manned by Veterans Administration doctors and require veterans to go to such clinics where available. Further, the Veterans Administration has prepared a schedule of fees which, while supposedly an attempt to arrive at a standard nomenclature, does contain a maximum fee for each service and has all of the ear marks of a nationwide schedule of fees.

The Council recommends to the House of Delegates:

1. That the Council on Medical Service be authorized to set up a conference for the purposes of arriving at a definite policy with regard to the Veterans Administration Home Town Medical Care Program.

2. That representatives from each of the state medical societies and representatives of the Veterans Administration be invited to this conference to present their views, experiences and opinions.

3. That, following this conference, the Council on Medical Service in collaboration with the Board of Trustees and representatives selected by the state societies be authorized to meet with representatives of the Veterans Administration to effect solution of any existing problems.

American Cancer Society Program

At the December meeting of the House of Delegates the Council presented a report on the American Cancer Society Service Program and recommended its approval. Approval was voted by the House.

To acquaint the state and county medical societies with the service program and their position in developing a local program, the Council has prepared a News Letter giving a résumé of the various activities open to county societies under the service program. Experience is now accumulating and problems are developing. While under the service program the county medical society has full authority to approve or disapprove any or all activities, it has become evident that uniform policies with reference to certain parts of the program might be of assistance to the county societies. Such policies, of course, must be developed from the experiences of programs actually in operation.

With this in mind the Council recommends and is preparing a study of the extent and experience of the programs now in operation and will report its findings to the profession. If policy changes or additions seem necessary, they will be reported to the Board of Trustees.

Cash Sickness Benefits

A study of cash sickness benefits was authorized in July 1946 but was not referred to the Council until March 1947. The Council has inquired briefly into the status of disability insurance providing temporary cash benefits for time loss due to nonoccupational disabilities. We find that there is much controversy concerning this type of insurance, particularly when it comes about as a result of either federal or state legislation. At the present time two of the states, Rhode Island and California, have adopted compulsory disability benefit laws. In general they follow the same pattern. They differ, however, in that Rhode Island sets up a monopolistic state fund for the purpose of supplying benefits, while the California law permits either the employer or a group of employees to establish a voluntary plan as a substitute for coverage under the state plan. Many defects seem to have become apparent in the Rhode Island program, and it seems to be the consensus that it provides only a negative lesson in that it shows certain features not desirable in a law but gives no experience to prove that even with these eliminated its operation would be satisfactory. The California plan has not provided sufficient experience to determine its worth.

The Council finds that some thirty-two "cash sickness" bills have been introduced this year in the legislatures of thirteen states. Twenty-two of these bills have failed to pass, one passed both houses but was vetoed by the governor, and nine are still under consideration.

The Council also points out that the action of Congress in amending the recent provision of the Railroad Retirement Act to provide disability benefits for railroad employees will likely serve to focus and intensify the interest of state legislators in compulsory disability benefit laws. There has, of course, been a rivalry between the state and federal governments in the field of unemployment compensation benefits, and a renewed drive for state legislation may well be expected. If this drive materializes the state medical societies will need aid in devising policies, and this will require a knowledge of developments under existing programs.

We must not forget that this type of compulsory program may well lead to expansion of social security legislation along the lines suggested by Senators Murray and Wagner and Representative Dingell. Therefore its benefits and defects must be reviewed in the light of principle as well as temporary accomplishment. The Council mentions this preliminary study of cash sickness benefits to call attention to its importance and to inform the delegates that a detailed study will be made so that the state medical societies will be in a position to meet possible future legislation.

Hospital Construction Act

The Council on Medical Service is watching the developments following the enactment of the Hospital Construction Act and urges all state associations to keep abreast of these developments.

The definition of health centers should be reviewed at this time by the House of Delegates. At the December meeting of the House of Delegates the Council was authorized to "prepare a suitable definition of a health center or of health centers of varying types." Dr. Dean F. Smiley, Consultant on Health and Physical Fitness of the Bureau of Health Education, has completed a study of health centers for the Council. A brief summary of the conclusions is available to members of the House of Delegates. The following summary of Dr. Smiley's report is referred to the House of Delegates without comment for its consideration:

Summary of Dr. Dean F. Smiley's Report

1. At least fourteen different functions have been assigned the health center since 1912.

2. Of these fourteen functions it is recommended that only five (communicable disease control efforts, sanitation, maternal-infant-child-hygiene measures, vital statistics and health education) be generally included under the title of public health center as that title is used in the Hospital Survey and Construction Act of 1946.

3. It is recommended that public health centers be established as needed (the Hospital Survey and Construction Act of 1946 definitely limits the number of such centers in thickly populated states to 1 per 30,000 people, in states having a population of less than 12 persons per square mile to 1 per 20,000 people) and in close proximity to hospitals and medical schools (if any) in base hospital service areas, intermediate hospital service areas and rural hospital service areas and that they be integral parts of base medical centers, district medical centers and community medical centers. It is, however, recommended that at every level the public health center be kept administratively independent.

4. Public health centers to serve as headquarters for county and multi-county public health units are much more urgently needed than are rural public health centers serving as extensions of county and multi-county public health units.

5. It is recommended that in rural communities of 4,000 to 18,000 in need of sick beds but not large enough to afford a 50 bed general hospital, "community clinics" of 10 to 40 beds be provided by hospital authorities rather than "public health and medical service centers" provided by public health authorities. However, administratively independent public health centers may to advantage be housed in the community hospital or community clinic.

6. In those rural communities where bed service is available from neighboring community hospitals and the urgent need is for facilities for public health and *diagnostic facilities* it is recommended that the public health center shall provide facilities not only for the traditional six point public health service but also for clinical laboratory service and limited x-ray service. Offices for the part time use of the practicing physicians of the community should also be included if the physicians so desire.

7. In the interests of economy and administrative efficiency it would appear generally wise to avoid combining medical service functions, hospitalization functions, welfare and social service functions or recreational functions with public health functions in the public health centers projected under the terms of the Hospital Survey and Construction Act of 1946. The public health center should, however, include facilities for meeting effectively any responsibility laid on the public health department by the local community.

ADDRESS OF REAR ADMIRAL JOEL T. BOONE

During the presentation of the supplementary report, Dr. McCormick requested and received approval of the House to hear the following address of Rear Admiral Joel T. Boone:

Mr. Speaker, Dr. McCormick, Members of the House of Delegates of the American Medical Association: I haven't had an opportunity to prepare, other than to jot down a few thoughts last night, what I might say if you were gracious enough, having been forewarned, to invite me to appear before you.

For the second time in six months I have been highly honored by this very distinguished body by invitations to address it. I am inexpressibly grateful for your tribute to an agent of medicine who has tried with a serious conscientiousness to apply his professional talents to an ailing patient, the bituminous coal industry. Furthermore, he has observed the omissions of public health (that does not mean the United States Public Health Service, I want to say) and the failure to apply preventive medicine and industrial medicine. Also he regrets he has seen medicine practiced to reflect no credit on the healing art, and very gratifyingly he has seen wonderful examples of the practice of medicine in certain areas of the bituminous coal mining area.

Happily, all the members in the family of coal were not ill, as some may have claimed. Owing to adherence to health concepts and practices, some of the members of that family were robust, vigorous and examples of a high degree of healthfulness.

Yesterday, Sunday, fittingly this convention started off with a religious note sounded in which a trio of exhorting voices were raised to inspire men. These men were worthy representatives of Almighty God. Dr. Hutchison, Rabbi Liebman and Monsignor Sheen elevated men's minds and souls to determine consecration to greater service to mankind. Each of these eloquent speakers knit the practice of medicine to the pattern of religion.

Would that I possessed a fraction of their power to bring to you a message from the group who made the medical survey of the bituminous coal industry as the director of that group. Of that survey I wish to say that the results obtained are those of a team and not of an individual. Each member of the group made his contribution.

As the appointed head of the mission, I approached my job as the physician. The survey was conceived and pursued as a medical problem, and never once did I lose sight of the fact that I was in my chosen role as the common practicing physician. In approaching the problem, I knew that I first had to make a diagnosis of the malady before I could possibly think in terms of a remedy.

In the preparation of our report we sought not to popularize ourselves by avoiding criticism. We had a responsibility and a goal of producing and presenting factual data and, in doing so, determined to be impartial. We did not straddle. As a physician, I knew that the diagnosis, the symptom complex, must be relieved.

Cooperation was attained quite readily, because I said to management and I said to labor "You may fight and row over wages and hours, but most certainly, gentlemen, health is a common concern."

We are indebted to management and labor and, as a representative of the medical profession, I feel very keenly our indebtedness as well to the state, federal and local authorities for their assistance and demonstrated cooperation. We could not have had more cooperation than we had, and we could not have attained the results we did without it.

Of course, we met with discouragement many times, and there were periods when I must say frankly that I felt frustrated. The challenge to success was omnipresent. As naval officers we were given a unique mission, a broad mission. We were definitely on the spot. Some of the members of this Association in Chicago at the headquarters said to me very frankly last summer and last fall that they were very gratified they did not have the responsibility.

For the first time in history, a national survey of a basic industry under governmental auspices was ordered to be conducted, and the Navy was given the assignment. The reaction has been beyond one's fondest expectations. It is gratifying, I assure you. But the disclosures present great challenges which must be embraced and successfully met. I have confidence that there is adequate leadership in industry—and I apply it not to the coal industry but to industry as a whole—and in my own profession, to overcome all the obstacles to the attainment of improved health for those individuals who contribute to the nation's welfare in the production of coal. With the coal industry as a means to an end, through it all industry, mechanical and agrarian, may be benefited and the health of the nation as a whole thereby raised to a higher level than we tolerate too complacently today.

Saturday I was asked to contribute to your Council's deliberations as to what to do, and I felt quite inadequate in a few moments to advise them. I would be very happy to cover the subject sometime as to my own ideas, if they have any value whatsoever, based on the experience in this survey. Among those recommendations I would like this one to stand out in italics, if possible. It appears under the section on Medical Care and Hospitalization:

"That an outstanding and recognized leader of the civilian medical profession be appointed a member of any trusteeship established, the purpose of which is for the medical care and hospitalization of miners and their dependents."

The other day, by a strange coincidence, I was invited by the president of the United Mine Workers of America to have luncheon with him. I was a bit apprehensive when I accepted, although I wanted to have a chance to talk to him to see how he felt about the report, because I thought there might be others present and it wouldn't be the relationship that we have as a physician with a patient alone. He personifies, in a way at least, the part of the patient.

After he had congratulated me much more fully than I expected, I said "I am surprised, Mr. Lewis, since I castigated your organization as I did."

He said to me "I don't mind what you said about our organization. You are one group that we felt we could have confidence in, that you would be factual, and I am satisfied because you have exposed the situation to public gaze."

Then I put up some challenges to him. I cannot repeat them all, but I would like to say to this group that I said to him "If you are going into the field of medicine, my advice to you, for the first time that you do, is to acquire the services and to get the advice of organized medicine, to get one of the most outstanding leaders in the profession of medicine to be your adviser and then pay him comparably to what you pay your legal talent. I understand you pay them as high as any other organization in the United States."

I might say also that after I had thanked him for the luncheon in a note later I said to him "You have gained great points for labor in wages and hours, but at your age in life, as you are coming to the end some years from now, you can overcome a lot of opposition to you and feeling toward you, and you could perform not only a great service to your union but to your country, if you gave yourself to the promotion of health. Until you champion preemployment, preplacement examinations, to which the union has shown opposition, you are not assuring yourself of the stability, mental competence and physical stamina of the individual who operates the machine. Mining has become very highly mechanized now, and you are failing in a great responsibility."

I said "If you come out and praise preplacement and preemployment examinations, all the opposition will be dissipated."

He said "I will do it," and I hope he will.

On Sunday I was congratulated several times, and one of my friends in this group was very fulsome in his congratulation. Then he said "I wonder whether anything will be done about it" and that gave me a thought. The profession of medicine can be a determining and a compelling force that there will be something done about it. Medicine is the guardian of the health of this nation, and we can't afford to permit known and disclosed serious and dangerous factors opposing health to continue to exist without something being done about it.

The other day, among many articles I have seen in magazines referring to this report of ours, I read one in the *Saturday Review of Literature* for May 10, and I understand that it is the first time this fine magazine has ever given any recognition to a governmental report. The writer was Mr. Starr, formerly on General MacArthur's staff, now in civil life. Among other things, he said:

"Public opinion will back this report if its contents are known and popularized by radio, play and movie. The presumption of effective democracy is that human beings can be persuaded. The minority can convince the majority if they have the facts on their side, but our powers of persuasion are not yet equal to the size of the case for improving the miner's lot. So far, the battle sectors of health and housing have not been manned in effective strength. This report is a valuable munition. Its criticisms and constructive recommendations are immediately practicable."

Gentlemen, in conclusion, if I may repeat from our report, the last paragraph reads:

"The report of the medical survey of the bituminous coal mine industry presents convincing evidence that the serious problem of improving the health of the miner, assuring him of better living conditions, enabling him to provide for his family through his own initiative and efforts and making him a more responsive and responsible citizen of his community, is a valuable problem if labor, management and the medical profession cooperate and work conjointly with a united interest and sincere devotion to a common cause: the good of large numbers of people in a basic industry. Health is a common concern of all groups. Working together for its promotion can help immeasurably to weld the bonds of human interrelationship."

Dr. McCormick expressed the desire and thought of the Council on Medical Service that Admiral Boone, members of the House of Delegates and physicians generally interested in this report appear before the reference committee and make any additional suggestions which they may have to make.

REPORT OF JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Dr. Ernest E. Irons, Chairman, presented the following report of the Joint Committee for the Coordination of Medical Activities, which was referred to the Reference Committee on Miscellaneous Business:

During the past year the Joint Committee for the Coordination of Medical Activities, formerly the Committee on Postwar Medical Service, has continued its discussions in well attended meetings. It is well understood by all members of the Joint Committee and by the organizations they represent that its work is advisory only. However, through its free and open discussions of many diverse problems confronting American medicine, the Joint Committee exercises a considerable influence toward the accomplishment of desirable objectives.

The Joint Committee is made up of officially appointed committees of the American Medical Association, the American College of Surgeons and the American College of Physicians and of liaison members representing the following organizations:

Advisory Board for Medical Specialties.
American Dental Association.
American Hospital Association.
American Pharmaceutical Association.
American Red Cross.
Association of American Medical Colleges.
Catholic Hospital Association.
Federation of State Medical Boards.
Federal Security Agency.
Office of the Surgeon General, United States Army
Bureau of Medicine and Surgery, United States Navy.
United States Public Health Service.
Veterans Administration.

The American Red Cross and the American Pharmaceutical Association were added to the liaison membership during the past year. Until the Procurement and Assignment Service and the War Manpower Commission were dissolved after the war, those government agencies also were represented on the Committee.

Since the report of the Committee was made to the House of Delegates in San Francisco, various matters have been discussed. Following a discussion regarding the postwar shift of the physician population, particularly with respect to rural areas, the American Medical Association's Bureau of Information undertook a survey to determine the conditions and distribution of medical care in the rural areas of the country. The initial report on this survey appeared in The Journal of the American Medical Association for May 17, 1947.

Important subcommittees of the Joint Committee have been active and have made informative reports which have been published in The Journal from time to time as a part of the minutes of meetings of the Joint Committee. Among these have been reports of the Subcommittee on Surplus Medical and Hospital Supplies, and on Graduate Education for Physician Veterans. The latter committee is still at work and has had frequent and cordial contact with officials of the Veterans Administration. Reports have been presented on licensure, mostly with respect to the licensure of physician veterans. The problem of licensure of foreign graduates also has been considered. A subcommittee on National Legislation for a Department of Health has been studying the various bills introduced into the Eightieth Congress which would establish in one manner or another a department or division of health in the federal government.

At its meeting in February 1947 the Joint Committee heard a statement from the American Red Cross concerning its proposed blood bank program. The Joint Committee found itself in agreement with the Board of Trustees of the American Medical Association, which endorsed the program in principle on the basis of community need and administration and of agreement by the local county medical society concerned.

A recent report had to do with the shortage of nursing personnel and with a plan sponsored by the American Hospital Association in cooperation with the National Nursing Council whereby a nurse recruitment program may be instituted.

A subcommittee on the Needs and Better Recognition of the General Practitioner has done considerable exploratory work. At the most recent meeting, April 26, 1947, this committee presented a report and recommendations which will appear shortly in The Journal.

The Joint Committee continues to be a forum in which the problems of American medicine can be discussed.

Respectfully submitted for the Committee,

Ernest E. Irons, Chairman.

REPORT AND SUPPLEMENTARY REPORT OF COMMITTEE ON RURAL MEDICAL SERVICE

Dr. F. S. Crockett, Chairman, presented the report of the Committee as contained in the Handbook and the following supplementary report, which were referred to the Reference Committee on Hygiene and Public Health:

On page 116 of the Handbook we reported the second annual conference with the major farm groups. Acting on the suggestions made at that time, your committee asked and received authority from the Board of Trustees to invite the American Farm Bureau Federation, the National Grange, the Farmers Educational and Cooperative Union and the National Cooperative Milk Producers Federation to appoint members to act in an advisory capacity to this Committee.

On May 24 the Committee met with its advisers to explore ways and means of getting action on the community or trade area basis. It was agreed that the formation of health councils should be undertaken on the state level and their development on the local level at the earliest possible moment. Their value in organizing sentiment for better health standards and initiating necessary measures to secure them cannot be duplicated by any outside organization.

Health councils requiring broad community participation would open the way for closer cooperation between the profession, farm and other groups and make possible any other desirable activity, such as prepaid medical and hospital plans, construction of hospitals or diagnostic centers, the bringing and holding of professional personnel, and so forth. It was the opinion of our advisory members that the organized farm groups would welcome the initiation of health councils and other health activities by the medical profession.

It was further agreed that news releases containing material pertaining to rural health should be sent from time to time to the farm organizations represented on this committee, this material to be used at their discretion in their publications to stimulate interest in rural community health problems

Discussion of medical cooperatives developed some interesting points of view. *It seems the action of the House of Delegates* last December, asking the Board of Trustees to formulate minimum standards necessary for good medical care, such as might be set up by consumer groups for example, medical cooperatives, would be welcome Our advisory members could not speak authoritatively for the cooperatives but in their opinion such a move by our profession might go a long way in creating a more friendly attitude

In the opinion of all our advisory members, the annual conference has been successful in convincing our farm friends of our interest in their health problems and should be continued. They *will meet with us next October in planning the next* conference.

Respectfully submitted,

F. S. Crockett, Chairman.
E. J. McCormick.
Victor Johnson.
C W. Roberts.
L W. Larson.
Fred A Humphrey.
Carll S. Mundy.

REPORT OF COMMITTEE TO STUDY REVISION OF CONSTITUTION AND BY-LAWS

Dr. F. F. Borzell, Chairman, presented to the House of Delegates the proposed revised Constitution and By-Laws, a copy of which had been sent prior to the session to each delegate, with the statement that some minor changes had been inserted to which he would call attention He stated that under the present Constitution and By-Laws the proposed revised Constitution would have to lie over until next year and began to indicate the modifications in the proposed revised By-Laws.

After discussion, it was moved by Dr T. K. Gruber, Michigan, *seconded by Dr. Thomas S. Cullen, Maryland, and carried that* this be read by title except such changes as Dr. Borzell desired to offer. Dr. Borzell began reading amendments to the revision but the delegates did not have copies with them and Dr. Borzell moved that the order of business be changed so as to include this report just previous to the beginning of the reports of the reference committees the next day The motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried

REPORT OF COMMITTEE ON MILITARY RANK

Dr. B. R Kirklin, Chairman, presented the following report, which was referred to the Reference Committee on Miscellaneous Business:

You have heard from the Surgeons General of the Army and Navy that bills are now before Congress which provide for increased rank and pay for the medical officers of the two services. They also stated that these bills have the blessing of the War and Navy departments

Therefore, since the purposes for which this Committee was created have been attained, as far as is possible at this time, the members of your committee recommend that the committee be discharged

Respectfully submitted,

B. R. Kirklin, Chairman
Hugh P. Smith.
Grover C. Penberthy.
Elmer Hess.

NEW BUSINESS

Resolution on Treatment of Plastics for X-Ray Visualization

Dr. Holman Taylor, Texas, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, There are about 15,000,000 children who play with toys that are made of plastic, rubber and other material which does not show in either x ray pictures or the fluoroscope, and for which reason they are a distinct hazard when swallowed; and

Whereas, Dr B H. Vaughan of Port Arthur, Texas, has started a campaign to have a federal law passed to require manufacturers of such toys to incorporate some harmless substance into the material from which they are made that will make them visible in x ray pictures; therefore be it

Resolved, That the State Medical Association of Texas go on record as endorsing the movement, and that our delegates to the American Medical Association be urged to introduce this resolution in the House of Delegates of that organization at its next session.

Resolution on Need of a Greater Income for Medical Schools

Dr Robert E Schlueter, Missouri, presented the following resolution, which was referred to the Reference Committee on *Medical Education*:

Whereas, Some medical schools are in need of a greater income to maintain their present high standards of instruction and scientific medical research; and

Whereas, It is actually impossible to increase the tuition fees sufficiently to secure the required funds, and

Whereas, Certain *schools of medicine are considering the organization* of clinics for the practice of medicine and surgery on a profit making basis in order to attain this end, and

Whereas, Such clinics would be in direct competition with the graduates of the medical schools involved as well as with all other practicing doctors of medicine, therefore be it

Resolved, That the House of Delegates of the American Medical Association *be requested to instruct the Council on Medical Education* and Hospitals to study this problem and find the proper means for combating this critical situation, which might even require an appeal to existing foundations or the creation of a new national voluntary foundation for the specific purpose of subsidizing approved medical schools which require financial assistance

Resolutions on Hospitals Entering Into the Practice of Medicine

Dr. Walter E. Vest, West Virginia, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, *There is a growing tendency among hospitals to enter into* and encroach on the practice of medicine, especially in the fields of pathology, clinical laboratory work, anesthesia and diagnostic roentgenology, and

Whereas, In all the states the practice of medicine is legally a franchise granted by the state to an individual after rigid technical training and due examination; and

Whereas, The practice of medicine involves an individual personal service which in the nature of things cannot be performed by an organization or corporation, and

Whereas, *In an increasing number of* hospitals, lay boards have gradually taken over the policies of the hospitals and have dictated to the medical staff not only problems of management but those of nursing and medical care as well; therefore be it

Resolved, By the House of Delegates of the West Virginia State Medical Association, that we go on record as condemning this tendency, especially as to setting and collection of fees by hospitals, and be it further

Resolved, that our delegates to the American Medical Association be instructed to present these resolutions to the House of Delegates of the American Medical Association at the coming session in Atlantic City with the request that the Council on Medical Education and Hospitals be instructed to include in the standards for hospital recognition these basic principles.

1. That all fees for medical service be set by and collected for by duly licensed doctors of medicine, and
2. That all policies and practices involving treatment, nursing and *medical service be approved by the medical staff before being put into* effect

Resolution on Establishment of a Section on Diseases of the Chest

Dr. Walter E Vest, West Virginia, presented the following *resolution,* which was *referred* to the Reference Committee on Sections and Section Work

Whereas, There are approximately 2,500 physicians and surgeons in the United States engaged *in the practice of diseases of the chest;* and

Whereas, This specialty has made notable progress in advancing the knowledge of diseases of the chest during the past ten years, and

Whereas, A total of 388 chest specialists registered at the annual session of the American Medical Association held at San Francisco, July 1-5, 1946; and

Whereas, The registration exceeded this total in but four of the seventeen sections of the American Medical Association, i e Internal Medicine, Surgery, General and Abdominal, Obstetrics and Gynecology, and the General Practice of Medicine, and

Whereas, Diseases of the chest constitute *a very large and important* segment of the entire volume of medical practice; therefore be it

Resolved, By the House of Delegates of the West Virginia State Medical Association, that our delegates to the American Medical Association be instructed to present this resolution in the House of Delegates at the coming session in Atlantic City, with the request that a Section on Diseases of the Chest be established in the Scientific Assembly of the *American Medical Association*

Resolutions on Rebates

Dr. William Weston, Section on Pediatrics, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

Whereas, Complaints have been made from time to time by individual members of the American Medical Association and by constituent associations of the existing practice of accepting rebates by members, and especially has this practice been emphasized in regard to oculists and opticians in which it has been charged that many oculists conspire with opticians by accepting rebates on prescriptions for glasses, and

Whereas, The knowledge of this practice has become so widespread that it has been the subject of criticism by the lay press and by politicians unfriendly to the American Medical Association, and

Whereas, The American Medical Association through the House of Delegates has officially condemned all rebate practices in whatever shape or form they may exist and has distinctly expressed the opinion that such practices are in violation of the ethics of the American Medical Association, therefore be it

Resolved, That the House of Delegates reiterate its condemnation of this practice by any member accepting rebates, and be it

Resolved, That the Secretary of the American Medical Association communicate this action to the various county societies forming the constituent associations and request that members accepting rebates be removed from the role of membership, unless such member or members promise to desist from such practice in the future and that the secretaries of the various county societies communicate their action in this matter to the Secretary of the American Medical Association

Resolution on Indoctrinating Medical Students with Philosophy and Ethics of Profession

Dr. T. K. Lewis, New Jersey, presented the following resolution, which was referred to the Reference Committee on Medical Education:

Whereas, The new social philosophy being evolved in this country has confronted organized medicine with many vital and perplexing problems, and

Whereas, The burden of meeting these problems and at the same time retaining those attributes which experience has taught are vital in maintaining the standards of medical care is now being borne almost entirely by the more mature members of our profession, and

Whereas, It is recognized that the doctor of tomorrow, who is the student of today, will be the future standard bearer of our profession, and

Whereas, There is a formative period of six to eight years wherein as student and intern he receives his scientific training and lays the foundation for his professional philosophy, and

Whereas, We believe that, to prepare properly the physician to carry on the work now being performed by organized medicine, his curriculum should be supplemented by a program that would indoctrinate him with the philosophy and ethics of our organization, which program should emphasize the relationship to and the responsibility of the doctor in meeting the social problems now confronting our profession, therefore be it

Resolved, That the American Medical Association inaugurate a program which will systematically contact every medical student in each approved medical school, also those recently graduated now serving internship or other postgraduate training, said program being designed to supplement his scientific training with such facts and information as will fulfil the desires incorporated in this resolution. Preference should be given to a brief recognized course of instruction within the curriculum of each approved medical school, or by any other practical means deemed proper by the American Medical Association.

Resolution on National Health Policy

Dr. T. K. Lewis, New Jersey, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

Whereas, It is possible and likely that some form of national health policy will come into being; and

Whereas, The American Medical Association recognizes the need of supplying the professional and administrative leadership at the local level necessary to furnish public health services and adequate medical care to the people of the nation, therefore be it

Resolved, That the following principles be promulgated under the leadership of the Board of Trustees, or appropriate Council.

1 Each component society will appoint the necessary committees to study the public health and medical care problems concerned, to supervise projects relevant to these problems

2 Each component society pledges itself to maintain a high standard of professional skills among the medical personnel assigned to these projects, and to supervise such activities with a view toward maintaining high scientific standards and preventing personal exploitation.

3 Each component society invites and welcomes the active participation in its scientific programs by the qualified medical and nonmedical personnel of the appropriate health and welfare agencies

4. The health and welfare agencies will render genuine cooperation with each component society in the implementation of these projects

5 The health and welfare agencies will select their part time medical personnel from lists furnished by, or with the approval of, each component society.

6 The health and welfare agencies will clear through each component society any grievances concerning medical personnel

7. The health and welfare agencies will protect the private practitioner and family doctor by discouraging treatment in preventive clinics and by returning to the family doctor any cases not suitable for examination or care at the health or welfare agency

8 The health and welfare agencies will not profit financially by the labors of any medical personnel working there

9 Each component society and the health and welfare agencies will seek the cooperation of dental, nursing and pharmaceutical organizations in a program fashioned to accord with these principles

10 Each component society and the health and welfare agencies will maintain continuing liaison with each other to implement these principles

Resolutions on Medical Care of Veterans

Dr James R. McVay, Missouri, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations

Whereas, The Congress of the United States enacted in 1946 Public Law No 293, which provided for the medical care of veterans and authorized the employment of professional personnel by the director of the Veterans Administration; and

Whereas, The provisions of Public Law No 293 give permission to the director of the Veterans Administration to employ personnel whose qualifications for administering medical care are limited because of educational attainments, and

Whereas, The medical personnel accepted for commission in the Medical Corps of the United States Army and the United States Navy was limited to those who were qualified as Doctors of Medicine; therefore be it

Resolved, By the House of Delegates of the Missouri State Medical Association, assembled in the eighty ninth annual session, that it disapproves of the employment of any person who claims to be educated in the healing arts for the medical care of veterans eligible to the benefits as provided by the acts of Congress for the medical care of veterans when said person was not acceptable to the Medical Corps of the United States Army and the United States Navy for commission as a medical officer; and be it further

Resolved, That the Sections of Public Law No 293 giving such permission should be repealed, and be it further

Resolved, That these resolutions be presented by the delegates from the Missouri State Medical Association to the House of Delegates of the American Medical Association at the next annual session of the House of Delegates of the American Medical Association

Resolutions on Teaching of Medical Economics in Medical Schools

Dr. James R. Reuling, New York, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

The House of Delegates of the Medical Society of the State of New York at its annual meeting on May 7, 1947 directed that the following resolutions be introduced.

Whereas, The training of medical students is to a great extent under the direction of full time teachers, many of whom have not been engaged in the private practice of medicine and may not be acquainted with the viewpoint of the practitioner of medicine on socioeconomic problems; and

Whereas, At a previous meeting of the House of Delegates of the American Medical Association, it was requested by the House that courses in economics be established in medical schools as soon as feasible; and

Whereas, Such program was delayed by the onset of war; therefore be it

Resolved, That the American Medical Association through proper channels take active steps to insure the presentation to all medical students in the United States of the viewpoint of the practitioner of medicine on socioeconomic problems, and be it further

Resolved, That the American Medical Association assist in the preparation of material and the securing of speakers, or in any other way that is deemed necessary to further the institution of such a program at the earliest possible date

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. James Q. Graves, Louisiana, and carried, the House went into Executive Session to listen to a special report.

The House reconsidered a motion admitting officers and executive secretaries of state medical societies into Executive Session

On motion of Dr. E Vincent Askey, California, seconded by Dr. E. S Hamilton, Illinois, and carried, only delegates and officers of the American Medical Association were allowed in Executive Session.

The House convened in Executive Session at 5:15 p. m. and reconvened in Regular Session at 6.15 p m.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by several, the House recessed at 6:15 p. m to reconvene at 9 a. m, Tuesday, June 10.

(To be continued)

Washington Letter

(From a Special Correspondent)

June 18, 1947.

Senate Committee Approves Health, Education and Security Department

The Fulbright-Taft bill to create a Department of Health, Education and Security in the federal government, headed by secretary of cabinet rank, was approved by the Senate Expenditures Committee. The bill calls for appointment of three undersecretaries to head up the three principal divisions of the department. The department's duty would be "to promote the general welfare of the people of the United States by aiding and fostering progress throughout the nation in the fields of health, education and public welfare and related services, contributing to individual, family and community well being." No authority would be given in the legislation to any federal official to exercise control over the operation of any state or local health, education or welfare agency. The new department would include the Federal Security Agency and its constituent units the U. S. Public Health Service, the Food and Drug Administration, the U. S. Office of Education, the Social Security Administration and several lesser agencies. Spokesman for the California Medical Association Dr. Lowell S. Goin expressed agreement with general principles of the bill but took issue with a number of provisions. He pointed out that there was confusion in the words "health" and "medical care," explaining "It seems to me that the federal government, if sincerely interested in health and welfare of the people, might well turn its attention to some of these other problems rather than attacking the minor fraction of the problem called medical care."

Commission Advocates Filling "Gaps in Medical Care"

President Truman's Advisory Commission on Universal Training advocated compulsory training of all young men as part of a security program to cost billions of dollars. Proposed was a $1,750,000,000 a year universal training plan for 18 year olds. Rapid demobilization of the armed forces was criticized, and it was pointed out that "our military forces" are now a hollow shell. Called for in the overall security program was "a strong, healthy, educated population." The commission "strongly urged passage of legislation to fill the gaps in medical care and education benefits for the entire nation as quickly as possible."

Fines in Artificial Limb Industry

Associated Justice Alexander Holtzoff assessed fines from $100 to $1,000 on five corporations and three individuals in the artificial limb industry who pleaded nolo contendere, or no contest, to charges aired in a District of Columbia court. All the defendants had previously been found guilty on the same charge by Federal Judge Bower Braddus of Oklahoma City in the same court on May 14, 1946, with a subsequent appeal upheld in the U. S. Court of Appeals. Fines were imposed as follows: J. E. Hanger Company of Washington, D. C., $500; subsidiaries of the Hanger Company in Illinois, $500; Texas, $500; Indiana, $250, and Missouri, $500; McCarthy Hanger, president of the Missouri firm, $1,000; Joseph F. Branham, vice president of the Illinois firm, $500, and Hugh H. Hanger, said to own a separate business in Philadelphia, $100.

Helps to Coordinate Eyesight Saving Plans

The Federal Security Agency's Office of Vocational Rehabilitation announced that federal and private efforts to aid persons who have poor eyesight but are not totally blind will be coordinated through the National Society for the Prevention of Blindness. Similar cooperative agreements have been made with eighteen other organizations interested in specific problems of physically handicapped persons.

Washington Hospitals Plan to Moderize

Should the bill introduced last week to authorize approximately 15 million dollars for modernization of the capital's hospitals be enacted, most Washington private hospitals are reported to be planning remodeling or expansion. Representative Mary T. Norton, Democrat of New Jersey, introduced the measure as an amendment to the 1946 Washington Hospital Center Act.

General Bradley Praises Work of Volunteers

Veterans Administrator Omar Bradley informed his agency's Voluntary Service National Advisory Committee that the work of volunteers is making it possible for World War II veterans to leave hospitals in better mental and physical condition than did World War I veterans. He said that the work of almost three hundred different voluntary service groups is "helping the patients in our veterans' hospitals toward an early recovery."

Richard F. Allen Slated to Head Foreign Relief Program

Legislators have disclosed that President Truman favors the appointment of Richard F. Allen, a Red Cross vice chairman, as head of the general foreign relief program which Congress has been giving final attention. The director of the project would be in charge of distributing medicine, food, clothing, fuel and other necessities to five European countries and to China.

Cancer Council Recommends Forty-Eight Grants

The National Advisory Cancer Council has recommended forty-eight cancer research grants to laboratories, hospitals and universities throughout the country, totaling $700,000 in value. Georgetown University, Warwick Memorial Clinic and Dr. Walter R. Kirner of the National Research Council, all in Washington, D. C., were recommended for $70,000 of the total. The grants are dependent on 1948 Congressional appropriations to the U. S. Public Health Service.

Homes for Paralyzed Veterans

The Senate Banking Committee heard witnesses testify in favor of legislation, opposed by the Veterans Administration, to provide specially built homes for paralyzed war veterans. Thirteen paraplegics were wheeled into the hearing room. Mrs. Robert Moss, wife of a crippled patient at Halloran Hospital, Staten Island, N. Y., pleaded for the special homes and declared that in standard homes paraplegics are "complete invalids." Another witness said the only alternative is "hospitalization for life." General Bradley, Veterans Administrator, told the committee in a letter that "if an exception were made in the case of paraplegic veterans . . . it would be difficult to deny similar consideration to other seriously disabled groups, such as blinded veterans, those suffering from serious heart and lung conditions, and many others."

Dr. Ross T. McIntire Heads District Health Council

Dr. Ross T. McIntire, former U. S. Navy Surgeon General and White House physician, has been named chairman of the Washington Metropolitan Health Council, succeeding Dr. Herbert P. Ramsey, chairman from the council's inception in 1944. Dr. McIntire promised to make the council a "real force in the metropolitan area." Howard Strong, former head of the Health Division, U. S. Chamber of Commerce, was named vice chairman. Appointments must be approved by the Council of Social Agencies.

Arlington Hospital Site

A Norfolk, Va., court order has been signed giving possession of the 25 acre Nevius Tract in Arlington County to the Veterans Administration as the site for its new Washington area veterans hospital.

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28-30. Dr. William J. Blanton, Juneau, Secretary.

American Orthopedic Association, Hot Springs, Va., The Homestead, June 27-30. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Physiotherapy Association, Pacific Grove, Calif., July 6-12. Miss Mildred Elson, 1790 Broadway, New York 19, Secretary.

American Urological Association, Buffalo, N. Y., Hotel Statler, June 30-July 3. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Maine Medical Association, York Harbor, Marshall House, June 22-24. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Minnesota State Medical Association, Duluth, June 30-July 2. Dr. B. B. Souster, Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Montana, Medical Association of, Missoula, June 26-28. Dr. H. T. Caraway, 115 N. 28th St., Billings, Secretary.

Wyoming State Medical Society, Sheridan, June 23-25. Dr. George E. Baker, 226 E. 2d St., Casper, Secretary.

GOVERNMENT SERVICES

ARMY

ARMY AWARDS AND COMMENDATIONS

Major General Norman T. Kirk

The United States of America Typhus Commission Medal has been awarded to Major Gen. Norman T. Kirk, Surgeon General of the Army, whose services were thus summed up in the citation: He rendered exceptionally meritorious service in connection with the work of the United States of America Typhus Commission from June 1, 1943 to June 30, 1946. Thoroughly comprehending the problems of typhus on a worldwide scale, he contributed in every way possible through his advice, special knowledge, high position and command of facilities to the effective operation of the commission in the United States and in all theaters overseas. By fostering investigations of rickettsial diseases and their control, General Kirk aided directly in achieving the new victory over typhus. Dr. Kirk graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1910 and entered the military service May 22, 1913.

Major General Paul R. Hawley

The awarding of the Distinguished Service Medal to Major Gen. Paul R. Hawley, medical director of the Veterans Administration, was accompanied with a citation calling attention to his exceptionally meritorious service as chief surgeon, communications zone, European Theater of Operations, from June 1944 to May 1945. His primary responsibility for the health of more than three million American military personnel was made doubly heavy by the care his command exercised over certain civilian populations, prisoners of war and Italian service units. He established a medical service that reached far forward to the battle lines to give superior attention to the wounded and rapidly evacuate them to areas where they could be speedily treated by completely modern methods. Through his unprecedented system it was possible to set a record of saving the lives of 96 out of every hundred wounded soldiers. The supervision of 318 hospitals and convalescent units, the evacuation of more than half a million casualties from the army areas and of nearly 200,000 to the United States was a task requiring the utmost coordination and superior management. Through his extensive professional knowledge and the aggressive, unremitting manner in which he applied it, General Hawley provided outstanding medical service to the armed forces in the European theater and made an important contribution to the war effort. Dr. Hawley graduated from the University of Cincinnati School of Medicine in 1914 and entered the military service in 1916.

Brigadier General Edward A. Noyes

The Legion of Merit has been awarded to Brig. Gen. Edward A. Noyes, M. C., U. S. Army, who, while serving as service command surgeon, Fifth Service Command, from July 1944 to December 1945, initiated exceptional medical practices and procedures at a time when casualties from overseas were overloading all hospitals and the patient personnel at the Convalescent Hospital increased fourfold in four months. He developed facilities for recreation, physical reconditioning and vocational training, instituted special treatment for neuropsychiatric and improved handling of paralyzed patients, and inaugurated at Fort Knox Rehabilitation Center a successful group therapy treatment program. Dr. Noyes graduated from the University of Oregon in 1913 and entered the military service in September 1915.

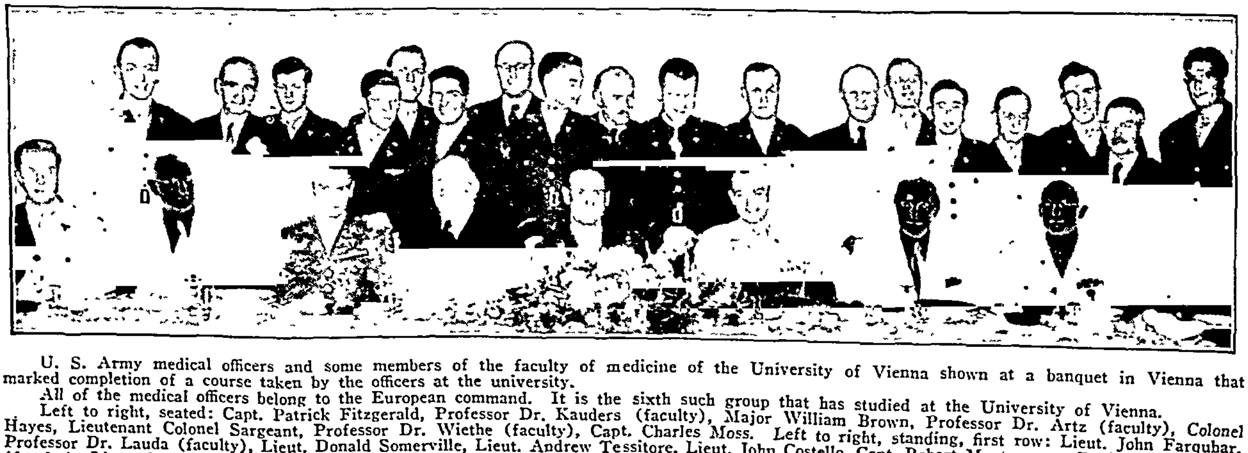
Colonel Wilford F. Hall

The Oak Leaf Cluster to the Legion of Merit has been awarded to Col. Wilford F. Hall, M. C., U. S. Army, who as surgeon of the Army Air Forces Personnel Distribution Command from July 1944 to May 1945 administered the physical reconditioning and educational programs in the Air Forces convalescent hospitals. By diligent application of his exceptional professional knowledge and superior judgment he played a leading role in rehabilitating combat veterans and making many of them available to the continental air forces and commands where they were vitally needed as replacements. Dr. Hall graduated from Washington University School of Medicine, St. Louis, in 1928 and entered military service in July 1928.

Lieutenant Colonel Everett W. Ryan

The Legion of Merit has been awarded to Lieut. Col. Everett W. Ryan, M. C., A. U. S., of Charleston, Miss., for exceptionally meritorious conduct in the performance of outstanding service as chief of preventive medicine section and medical inspector for the United States Army forces in the South Atlantic from September 1942 to September 1945. His superior judgment, long-range planning and inspired leadership are credited in the citation for succeeding in bringing about a most successful preventive medicine program during this period. The remarkable freedom from disease for our forces serving in an equatorial and subequatorial climate, in spite of almost unsurmountable environmental obstacles, was due in a great measure to the outstanding performance of duty of Lieutenant Colonel Ryan. Dr. Ryan graduated from the University of Louisville School of Medicine in 1934 and entered military service in May 1942.

MEDICAL OFFICERS COMPLETE GRADUATE COURSE



U. S. Army medical officers and some members of the faculty of medicine of the University of Vienna shown at a banquet in Vienna that marked completion of a course taken by the officers at the university.

All of the medical officers belong to the European command. It is the sixth such group that has studied at the University of Vienna.

Left to right, seated: Capt. Patrick Fitzgerald, Professor Dr. Kauders (faculty), Major William Brown, Professor Dr. Artz (faculty), Colonel Hayes, Lieutenant Colonel Sargeant, Professor Dr. Wiethe (faculty), Capt. Charles Moss. Left to right, standing, first row: Lieut. John Farquhar, Professor Dr. Lauda (faculty), Lieut. Donald Somerville, Lieut. Andrew Tessitore, Lieut. John Costello, Capt. Robert Montgomery, Professor Dr. Chiari (faculty), Lieut. Robert Kiley, Professor Dr. Lindner (faculty). Left to right, standing, second row: Lieut. James Gilboy, Capt. William Doremus, Professor Dr. Fellinger (faculty), Professor Dr. Antoine (faculty), Capt. Stephen N. Jones, Lieut. Robert Williams, Lieut. John Morris, Lieut. James Keehan and Capt. Carl Kundert.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Drs. Pottenger and Evans Receive Tuberculosis Awards.—Dr. Francis M. Pottenger, Monrovia, former vice president of the state board of public health, has received the medal from the California Tuberculosis and Health Association in recognition of his outstanding services in tuberculosis work. Dr. Pottenger was a guiding force in the organization of the Southern California Anti-Tuberculosis League, and its past president. Dr. George H. Evans, Berkeley, received a similar award. Both he and Dr. Pottenger are the only living members of the first committee appointed in 1904 by the California Medical Society to begin a study of tuberculosis in California.

Honorary Degrees for $25.—A copy of the following letter to a doctor of naturopathy in Dallas, Texas, has been received from the Texas State Board of Medical Examiners:

> THE UNIVERSAL EDUCATIONAL GUILD
>
> 6411 Hollywood Blvd. Hollywood 28, California.
>
> April 1, 1946.
>
> Dr. ————————, B.A., N.D.
> Dallas 4, Texas.
>
> Dear Doctor:
>
> In answer to your questions concerning the Guild please note the following: We are able to assist you in obtaining such Honorary degrees as Ph.N., M.N., Ps.D., Ph.D., LL.B., LL.D. et cetera. And from such schools as the following: The Southern College of Naturopathic Physicians and Surgeons; the Memphis College of Naturopathy; the Southern College of Psychiatry; the College of Drugless Healing; the American Health Association; "B.A., B.S., M.S., D.Sc., Ps.D., Ph.D.," and so on. The total cost to you for either of these degrees will not be more than $25.00 as all these institutions of learning are Members of the Guild and have agreed upon the above mentioned. The N.D.Sc. can also be obtained. If you desire to secure your M.S. (Honorary) this too can be arranged. The cost is the same. It will be impossible for non-Members to receive either of these Honorary degrees. As was mentioned in our previous letter that should you fail to receive perfect satisfaction while a Member of the Guild we shall return your Membership dues plus the 8% interest. I will personally assist you in preparing the necessary thesis for either of the Honorary degrees. I am often referred to as a "Ghost Writer." Granting you understand this term you will also realize that you may be sure of obtaining the degree of your choice. The necessary educational qualifications on your part doesn't matter. For you must understand that Honorary degrees are not based upon the same prerequisite academic training. When considering the cost of grading your thesis or examination (of Honorary nature) and the printing and mailing of your Diploma approximately $25.00 will have been spent on same.
>
> I have been engaged in this work for eleven years and so far of the 2254 Members who have joined during these years not one has so far requested his Membership withdrawn from our files.
>
> Then, too, Doctor, you must remember that we offer you other fine Services.
>
> Your only obligation to the Guild will remain the same as it has been for the past 11 years: $10.00 to join and $2.00 each year to belong.
>
> It will be a pleasure to hear from you again Doctor ———.
> With best wishes, I am,
>
> Very sincerely yours,
> /S/
> Dr. N. W. Nichols, M.D., N.D., Ph.D.
> President.
>
> NN:K
>
> P.S. I am a licensed D.C., D.O., M.D., N.D.
> Also, a member of the Bar—LL.B., LL.D.
> Hold my Ph.D. in Pholology, Philosophy, Bible, et cetera.

COLORADO

Establish Rheumatic Fever Library.—The Colorado Rheumatic Fever Library has been established at the University of Colorado School of Medicine, Denver, in an effort to assemble in one place all that has been written on the subject of rheumatic fever. Efforts will be made to collect all available reprints or photostatic and typewritten copies of them. The material will be cross indexed and assembled in bound volumes by years. The collection will eventually be made available to all workers in this field. Libraries, medical journals and those writing in the field of rheumatic fever can assist by contributing papers relating to the subject. The library has been made possible through the financial assistance of the Ladies Auxiliary of the Rocky Mountain Screen Club and the services of volunteers working under the direction of the Denver Area Rheumatic Fever Diagnostic Service. Information may be obtained by writing Dr. Ward Darley, Dean, University of Colorado School of Medicine and Hospitals, 4200 East Ninth Avenue, Denver 7.

ILLINOIS

Pioneer Woman Doctor Awarded Medal.—The Henry County Medical Association last month awarded a gold medal to Dr. Hattie B. Meliak, Kewanee, who has practiced medicine in that city for fifty years.

Spotted Fever in Illinois.—Three cases of spotted fever have been reported in southern Illinois, according to Dr. Roy Harrell, state district health officer. Health officials have issued warnings to avoid tall grass, weeds and undergrowth where the ticks could be picked up.

Society News.—The Peoria Medical Society heard Dr. Myron D. Miller, Washington, D. C., Tuberculosis Control Division, U. S. Public Health Service, discuss "Recent Developments in Management and Control of Tuberculosis" at its meeting May 20.

Chicago

Filth in Some Soft Drink Bottling Plants.—The advisory committee of the Chicago-Cook County Health Survey released on June 15 a report on a survey of twenty-eight of the city's fifty carbonated beverage and seven bottled water plants. The investigators made the study in February 1947, and the report was prepared by the U. S. Public Health Service as a part in its audit of health conditions requested by Chicago and Cook County governmental agencies. Much of the 175 million pints of soft drinks which Chicagoans drink each year is said to be manufactured under insanitary conditions and operating methods. Among the sanitary defects listed in the report are the following: 1. The surroundings of nine of the plants surveyed were described as filthy. 2. Toilet facilities in eleven plants were either lacking, in need of repair or dirty, and twenty-four of the plants did not have cleaning and washing facilities. 3. In many of the plants personal cleanliness was neglected and employees' clothes were dirty. In most cases employees were wearing their regular clothes and had not been furnished with washable outer garments to be used only for plant duty. 4. The methods used in handling, storage and preparation of ingredients were deplorable. 5. Dirty floors were noticed in ten of the plants, and in fifteen the walls and ceilings were badly in need of repair. 6. The storage and handling of caps, corks and other closures in dirty bins was very common. 7. In only one plant were the bottles properly protected with overhead shields from the bottle washer to the filler in order to prevent contamination. 8. Lack of covers on syrup tanks to prevent contamination from dust, flies and vermin was evident. 9. Several plumbing connections which would allow waste water to siphon back into drinking water supply were noticed in various plants. (All the carbonated beverage plants used the municipal water supplies in making their beverages.)

The majority of the defects in the six bottled water plants surveyed were similar to those found in the carbonated beverage plants. In addition, however, the investigators pointed out other insanitary conditions. For example, the practice of shipping water from out of state to Chicago in thirty gallon steel drums for rebottling presents a public health problem. These drums collect dust around the pouring hole, which can easily contaminate the water unless sufficient precautions are taken. Some of the plants surveyed were using a special spout for handling this water, but it was either not of a sanitary type or was handled improperly and given no bacterial treatment. Sanitary inspections of bottling plants located outside Chicago have never been made by local authorities, and this failure is due to a lack of proper city ordinance and to inadequacy of the inspection staff. The survey found also that the lack of suitable legislation covering the public health aspects of this important industry on both state and local levels is deplorable. Neither the city of Chicago nor the state of Illinois has modern ordinances on this subject. The survey recommended that an ordinance be adopted, at once, similar to that of the sanitary code of the American Bottlers of Carbonated Beverages, providing for the regulation of sanitation and distribution of all phases of the beverage and bottled water industry.

LOUISIANA

Intestinal Tumors of Dysenteric Origin.—In the paper by this title in The Journal, April 5, page 994, one of the footnotes is as follows: "From the Southern Baptist Hospital and Lakeshore Hospital, New Orleans." The director of the Touro Infirmary, New Orleans, writes that 2 of the cases quoted were patients in Touro Infirmary and that two of the six cuts in the article are from the records of Touro Infirmary.

Appoint New Professors.—The School of Medicine, Louisiana State University, New Orleans, has announced the following appointments: Dr. James D. Rives, formerly clinical professor of surgery, as professor and head of the department of surgery. Dr. Rives succeeds Dr. Urban Maes, who has retired and has been appointed professor emeritus. Drs. Joseph A. Danna and Narcisse F. Thiberge have also reached the age of retirement and have been appointed clinical professors emeritus of surgery and medicine, respectively. Dr. Sidney S. Chipman, formerly in the practice of pediatrics at Norwalk, Conn., and during the past year a student in the School of Public Health, Yale University, will be associate professor of pediatrics on a full time basis. Dr. Chipman will be director of the postgraduate extension program in pediatrics in the state of Louisiana on a joint appointment of the state university and the state board of health.

MASSACHUSETTS

State Medical Election.—At a meeting of the Massachusetts Medical Society, May 20-22, the following officers were elected: Drs. Edward P. Bagg, Holyoke, president; Daniel B. Reardon, Quincy, president-elect; Charles J Kickham, Boston, vice president; Joseph Garland, Boston, secretary; Eliot Hubbard Jr., Cambridge, treasurer, and Norman A. Welch, Boston, assistant treasurer.

Duncan Reid Appointed Professor of Obstetrics at Harvard.—Dr. Duncan E. Reid, Boston, will become William Lambert Richardson professor of obstetrics at Harvard Medical School, Boston, and obstetrician in chief to the Boston Lying-In Hospital on July 1, to succeed Dr. Frederick C. Irving, who resigned both positions Dec. 31, 1946. Dr. Reid has been on the staff of the Lying-In Hospital since 1933 and on the staff of Harvard Medical School since 1935. He received his medical degree from Northwestern University Medical School, Chicago, in 1932 and served as an intern and resident in the Passavant and St. Luke's Hospital of that city before going to Boston. His research in the field of obstetrics covered such subjects as pregnancy complicated by hypertension and albuminuria, the treatment of vomiting in early pregnancy, cardiac asthma and acute pulmonary edema as a complication of the toxemias of pregnancy and the treatment of prolonged labor.

MICHIGAN

Appoint Superintendent of Sanatorium.—Dr. W. Leonard Howard has been appointed medical superintendent of Wm. H. Maybury Sanatorium at Northville. A graduate of Queens University Faculty of Medicine, Kingston, Ont., he has been medical director of the American Legion Hospital, Battle Creek, for more than nine years and for the last five years has been medical director and superintendent of the Arthur S. Kimball Sanatorium. Maybury, an 846 bed sanatorium, is one of two institutions in the Detroit municipal sanatorium setup and one of the largest tuberculosis hospitals in the country. Dr. Howard succeeds Dr. Henry S. Willis, resigned.

MINNESOTA

State Medical Meeting at Duluth.—The annual meeting of the state medical association will be held June 30 to July 2 at the Duluth Hotel, Duluth, under the presidency of Dr. Louis A. Buie, Rochester. Out of state speakers include Drs. Robert E. Gross, Boston, specialist in heart surgery; George E. Shambaugh Jr., Chicago; Marcy L. Sussman, New York, who will deliver the annual Russell D. Carman Lecture in radiology; T. Benedict Massell, Boston; John R. Neffe, National Research Council, Philadelphia; Joseph G. Molner, Detroit; Haven Emerson, New York; Dean Smiley and Fred V. Hein, Chicago, of the American Medical Association. Twenty round table luncheons will be held at 12:15 Tuesday and Wednesday at which recent developments in scientific medicine will be discussed. "Rural Health—A Joint Responsibility" is the subject for discussion following the annual meeting. The first annual A. J. Sanford Lecture will be delivered by Dr. Elexious T. Bell, department of pathology, University of Minnesota, Minneapolis, on "The Pathology of Diabetes Mellitus." At the annual banquet Tuesday at 7 p. m. Fifty Club certificates and pin and the Southern Minnesota Medical Association Medal for the best individual scientific exhibit will be presented. All physicians who served in World War II are invited to a luncheon meeting at 12:30 Monday in the Tally-Ho Room, Holland Hotel, sponsored by the Society of Medical Veterans in Duluth.

MISSISSIPPI

State Medical Election.—At the annual meeting of the Mississippi State Medical Association in Biloxi, May 6-8, Dr. Reuben B. Caldwell, Baldwyn, was made president-elect. Dr. Paul G. Gamble, Greenville, is president. Registration for the meeting was about 380. Among the visitors were Dr. George F. Lull, Secretary and General Manager of the American Medical Association; Mr. C. P. Laranz, secretary-manager of the Southern Medical Association, and Dr. Rudolph Matas, New Orleans. The 1948 meeting is to be held in Jackson next May.

NEW JERSEY

Passaic County Society Celebrates Centennial.—Passaic County Medical Society celebrated its centennial in Paterson May 20-21. The scientific program included Dr. Irvine H. Page, director of research, Cleveland Clinic, Cleveland, who spoke on "Modern Concepts and Medical Management of Arterial Hypertension"; Dr. T. Duckett Jones, assistant professor of medicine, Harvard Medical School, Boston, "Diagnosis and Management of Acute Rheumatic Fever"; Drs. Milton J. Raisbeck, associate professor of medicine, and Samuel A. Thompson, associate professor of surgery, both of the New York Medical College, New York, "Practical Problems in Coronary Disease." The speaker at the centennial banquet was Dr. Max M. Peet, department of surgery, University of Michigan Medical School, Ann Arbor, on "The Surgical Treatment of Hypertension."

NEW YORK

Diabetes Association.—On April 13 the Rochester Regional Diabetes Association was formulated as a subdivision of the American Diabetes Association. Dr. Charles B. F. Gibbs, who heads the new society, organized the first diabetes clinic at Rochester General Hospital in 1925 and served as its chief for twenty years. He is a past president of the Rochester Academy of Medicine and chief of the Diabetes Clinic at Strong Memorial Hospital. Dr. Bernard A. Watson, Clifton Springs, N. Y., was named first vice president and Dr. David F. McGarvey second vice president. Dr. H. Raymond Drysdale, Rochester, is secretary-treasurer.

Atomic Energy Commission Study in Japan.—Dr. John S. Lawrence, associate professor of medicine, and Dr. Herman E. Pearse Jr., associate professor of surgery, at the University of Rochester School of Medicine and Dentistry, Rochester, have been assigned by the Atomic Energy Commission to a three month study in Japan in connection with the atomic bomb casualties at Hiroshima and Nagasaki. They left Rochester on June 2. Dr. Lawrence was attached to the wartime atomic medical research project at the School of Medicine and Dentistry under the Manhattan Engineer District for nearly four years. Dr. Pearse was a member of the radiological safety task force under Col. Stafford L. Warren, formerly professor of radiology at the Rochester Medical School and chief of the medical section of the Manhattan Project, in the atomic bomb test at Bikini last year.

New York City

Personal.—Dr. Milton B. Plotz has been elected attending physician, Kings County Hospital, Brooklyn, Long Island College of Medicine Division, and visiting physician, Bushwick Hospital, Brooklyn.

Warn Against Contaminated Shellfish.—A warning that shellfish taken from Jamaica, Pelham and Eastchester bays are contaminated and should not be eaten was issued June 6 by Health Commissioner Israel Weinstein. Shellfish taken from the polluted waters of these bays are likely to cause typhoid and other serious intestinal diseases. Swimming also is prohibited. Additional health department inspectors have been assigned to the areas to enforce the health department's sanitary code.

OHIO

State Medical Election.—At the annual meeting of the Ohio State Medical Association in Cleveland last month Dr. Ralph L. Rutledge, Alliance, became president and Dr. Arthur A. Brindley, Toledo, was chosen president-elect. Cincinnati was selected as the convention city for 1948.

Belgian Professor Gives Hanna Lecture.—The fifty-first Hanna Lecture of the Academy of Medicine of Cleveland was delivered by Dr. Norbert Goormaghtigh, professor of pathology, University of Ghent, visiting professor, Commission for Relief in Belgium, May 12 in Cleveland. His subject was "The Anatomical Basis of the Autonomy of the Renal Circulation." The Hanna Lectures were established in 1913 by Dr. George W. Crile in honor of Mr. H. Melville Hanna, an industrialist of Lisbon, Ohio, primarily to take advantage of the presence in this country of distinguished scientists for lectures on subjects of interest to medicine.

PENNSYLVANIA

District Society Meetings.—The Eighth Councilor District of the Medical Society of the State of Pennsylvania will hold its annual meeting June 25 at the Kahkwa Club west of Erie. The speaker will be Dr. Armando Trabuco, urologist of Argentina. During the afternoon session the president of the state society will present fifty year testimonials to the honor guests, Drs. Clyde L. Williams, Linesville; John Ackerman, Erie; Charles E. McCune, West Springfield; David A. Brown, Greenville; Willard B. Campbell, Harrisville; Judson C. Cooley, Sandy Lake; George W. Kennedy, Sharon, and Charles H. VerMilyea, Russell. The Third, Fourth and Twelfth Councilor Districts will meet at the Hotel Sterling, Wilkes-Barre, on June 25. On the scientific program will be Dr. Charles L. Brown, Philadelphia, "Differential of Hyperthyroidism"; Dr. Thaddeus L. Montgomery, Philadelphia, "Management of Toxemias of Pregnancy"; Dr. Louis H. Twyeffort, Philadelphia, "Psychiatric Problems Encountered in General Practice"; Dr. Monroe J. Romansky, Washington, D. C., "The Current Status of Penicillin Therapy—Uses and Abuses," and Dr. Irving J. Wolman, Philadelphia, "The Rh Factor." Fifty year testimonials will be presented to Drs. Calvin J. Balliet, Lehighton; John E. Fretz, Easton; Rossitter J. Lloyd, Olyphant; Agnes Sholly Knights, Selunsgrove; John K. Love, Easton; John R. Dyson, Hazelton; Frederick W. Roberts, Plymouth; John E. Scheifly, Kingston, and Earl E. Wagner, Wilkes-Barre.

Philadelphia

Personal.—Dr. Henry P. Brown Jr. left early this month for interior China, where he plans to spend four years as a medical missionary. He has been on the staff of Pennsylvania and Pittsburgh hospitals and a clinical adviser in surgery at the University of Pennsylvania School of Medicine, Philadelphia, of which he is a 1912 alumnus.

Effort to Detect Pelvic Cancer Early.—The Philadelphia Obstetric Society, in conjunction with the department of public health and the Philadelphia County Medical Society, has formed a committee chiefly of gynecologists to aid in preventing delay between the time the first symptom of pelvic cancer appears and the inauguration of proper treatment. All cases of the disease in hospitals in the city are to be reviewed by this committee, and when a delay has occurred in the institution of proper treatment the patient's former attending physicians and gynecologists are invited to a meeting in order to determine the cause and decide how such a delay can be avoided.

Pittsburgh

The Mellon Lecture.—The thirtieth Mellon lecture, sponsored by the Society for Biological Research of the University of Pittsburgh School of Medicine, was delivered May 29 by Donald Van Slyke, Ph.D., Rockefeller Institute of Medical Research, on "Studies of Renal Physiology."

TENNESSEE

New Law Requires Annual Registration.—Chapter 9, Public Acts of 1947, of the State of Tennessee becomes effective July 1. Among other things the law requires that all persons who hold a license to practice medicine in Tennessee must register and pay a fee of $2.50 some time between July 1 and Sept. 30, 1947. Failure to register will result in automatic revocation of the license to practice. On or before Dec. 31, 1947, and on or before each succeeding December 31, all licensees must register and pay a fee of $5. Failure to register by Jan. 31, 1948 and each succeeding January 31 will result in revocation of license. After the first registration, licensees who have retired from practice or who are practicing in other states may submit an affidavit of retirement on forms provided. Commissioned medical officers in the U. S. Army, Navy and Public Health Service are relieved from registration but must register within thirty days after discharge from service. Registration and retirement forms may be obtained from Dr. Robert H. Hutcheson, executive officer, State Licensing Board for the Healing Arts, 420 Sixth Avenue, North, Nashville 3, Tenn.

UTAH

Dr. George Sayers Awarded the Abel Prize.—At the annual meeting of the American Society for Pharmacology and Experimental Therapeutics, held in Chicago May 18-22, the John J. Abel Prize in pharmacology was awarded to George Sayers, Ph.D., assistant professor of pharmacology in the University of Utah School of Medicine, Salt Lake City. Dr. Sayers won the prize for his paper entitled "The Pituitary-Adrenal System." This prize of $1,000 and a bronze medal, plus an additional amount up to $150 for traveling expenses, was established in the society by Eli Lilly and Company for the purpose of stimulating fundamental research in pharmacology in the United States and Canada.

VIRGINIA

Memorial Exercises at Medical College.—Major Gen. David N. Grant, formerly air surgeon, U. S. Army, delivered the address at the memorial exercises of the Medical College of Virginia, Richmond, May 30. A plaque in commemoration of the personnel of the 45th General Hospital who died in the service of their country, was presented to President William T. Sanger by Colonel Powell Williams, unit director and chief of the medical service. A portrait of Dr. Frederick W. Shaw, Richmond, until his death professor of bacteriology, was presented to the college by Charles H. Meeks, president of the senior class in medicine.

Personal.—Dr. Philip St. L. Moncure, since 1897 a member of the medical staffs of St. Vincent's Hospital and the Hospital of St. Vincent De Paul, Norfolk, was honored May 8 at a testimonial banquet and reception celebrating his golden jubilee anniversary.——Dr. Clara C. Joel Fleischer has been named director of maternal and child health of the city department of health of Richmond, a newly created post. She will develop a citywide program of maternal, infant and preschool health. An American citizen, Dr. Fleischer is a pharmacy graduate of Prague, Czechoslovakia, and received her doctor of medicine degree from the Medical College of Virginia, Richmond. She has been in charge of the night venereal disease clinic at the college on a part time basis since 1943, as well as industrial physician at du Pont.

GENERAL

Medical Women's International Congress.—The Medical Women's International Association will hold its Fifth Congress June 24 to 30 in the Indian Institute, Amsterdam, Holland. The scientific program has been planned together with visits in Amsterdam and its surroundings as well as to various institutions.

Plague Infection.—United States Public Health Service, in its public health report for May 16, states that on April 21 and 22 proved plague infection was reported in ectoparasites from rodents in Arizona and Washington. In Navajo County, Arizona, fleas and a tick from two ground squirrels proved positive, and Yakima County, Washington, fleas from one ground squirrel and field mice proved positive.

Twelve Nations Ratify Constitution of World Health Organization.—Thus far twelve nations have ratified the World Health Organization constitution: Liberia, Ethiopia, Switzerland, Transjordan, Italy, the Netherlands, China, United Kingdom, Canada, Iran, New Zealand and Syria. A total of twenty-six ratifications by members of the United Nations are required for the World Health Organization to become a specialized agency of the United Nations.

Grant for Allergic Research on Multiple Sclerosis.—The Association for Advancement of Research of Multiple Sclerosis, Inc. made its first grant for specialized research on the disease June 11. The sum of $64,350 will cover three years of research in the field of allergy in connection with multiple sclerosis and will be under the direction of Elvin A. Kabat, Ph.D., assistant professor of bacteriology of Columbia University College of Physicians and Surgeons. The society was formed less than a year ago.

Association of American Physicians Meeting.—The Association of American Physicians at its annual meeting in Atlantic City, May 7, elected Dr. Alva H. Gordon, Montreal, Canada, president; Dr. Francis G. Blake, New Haven, Conn., vice president; Dr. Walter Bauer, Boston, treasurer, and Dr. Henry M. Thomas Jr., Baltimore, secretary. The George M. Kober Medal was presented to Dr. Eugene F. Du Bois, New York, professor of physiology, Cornell University Medical College, for his contributions to investigative and clinical medicine.

International Congress on Mental Health.—This congress, which will be held from August 12 to 21 in London, England, will consist of three conferences: (1) International Conference on Child Psychiatry, which will hold morning sessions August 12-15; (2) the International Conference on Medical Psychotherapy, which will hold afternoon sessions August 12-15, and (3) International Conference on Mental Hygiene, meeting August 16-21. Sessions will take place at Central Hall, Westminster. Subjects to be discussed at the conferences are Foundations of Mental Health in Childhood, Guilt, and Mental Health and World Citizenship. Inquiries should be addressed to: The Organizer, International Congress on Mental Health, 39 Queen Anne Street, London, W. I., England.

Danish Library Desires Back Issues of The Journal.—The University Library, Copenhagen, Denmark, has made a request for certain bound volumes of THE JOURNAL. The request, signed by Torkil Olsen, library assistant, Department 2-Nr. Allé 49, Copenhagen, Denmark, follows: "Due to the very great demand for THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION it has been decided to make an attempt to procure a set of Vols. 106-133 for shelving in the library's reading room. I am therefore taking the liberty to ask you kindly to insert a short note in THE JOURNAL to the effect that our library is anxious to have the particular volumes (106-133), and that we should be grateful in case a doctor of Danish descent would send these volumes or some of them to our library. All expenses in connection with the forwarding will be covered by our library."

Medical Aid to China.—At the annual meeting of the American Bureau for Medical Aid to China in New York City, April 12, Magnus I. Gregersen, Ph D., was elected president on the retirement of Dr. Donald D. Van Slyke, president for the past six years. Dr. Gregersen has been head of the physiology department of the College of Physicians and Surgeons, Columbia University, since 1937. Five new members elected directors are Edmond V. Cowdry, Ph.D., head of the anatomy department, Washington University, St. Louis; Dr. James A. Crabtree, assistant surgeon general, U. S. Public Health Service, Washington, D. C.; Dr. Howard C. Naffziger, professor of surgery, University of California Medical School, Berkeley-San Francisco; Miss Gertrude E. Hodgman, dean of the Peiping Union Medical College School of Nursing until 1940, and John T. Tripp, Ph.D., associate director, bureau of laboratories, Michigan Department of Health, Lansing.

CANADA

Art and Camera Salon.—Canadian Physicians' Fine Art and Camera Salon will be held in the Hudson's Bay Auditorium, Winnipeg, June 23-27, in conjunction with the convention of the Canadian Medical Association. Two bronze plaques will be presented, one to the winner of the Fine Arts section and one to the winner of the Photographic section.

Public Health Officers Honored.—At a joint dinner of the Canadian Public Health Association and the State and Provincial Health Authorities of North America in Quebec May 22 certificates of honorary membership of the Canadian Association of Public Health were presented to Dr. Thomas Parran, surgeon general of the United States, and to Dr. Walter L. Bierring, president of the State and Provincial Health Authorities of North America and commissioner of health of Iowa, both of whom addressed the group.

National Cancer Institute of Canada Created.—To coordinate all efforts in the cancer field in Canada on a national basis, the minister of the National Health and Welfare called a conference of representatives from all organizations working in the cancer field in Canada, as a result of which the institute was organized. It will (1) provide for the education and subsistence of cancer research workers; (2) attract more men into the program begun by the Canadian Association before the war by providing undergraduate and postgraduate education for physicians, and attempting to establish a uniform system of reporting cancer cases and deaths throughout the dominion; (3) continue the lay educational program now being conducted by the Canadian Cancer Society, and (4) raise funds to support the work of the institute. Dr. Allan W. Blair, Regina, Sask., was recently appointed managing director. The first project planned by the institute is an immediate survey of all cancer facilities for diagnosis, treatment and research in the dominion.

LATIN AMERICA

New Sanatorium in Chile.—Dedication of the 500 bed Trudeau Hospital at Santiago, Chile, took place March 27. Built jointly by the coordinator of Inter-American affairs of the United States and the government of Chile, the hospital will be under the direction of Dr. Rafael Lorca O., who has been appointed as superintendent and medical director.

Dr. Bernardo Houssay Receives Research Award.—The American Pharmaceutical Manufacturers' Association presented its first annual research award April 28 to Dr. Bernardo A. Houssay, Buenos Aires, Argentina, at its annual meeting in Boca Raton, Fla. The award was presented to Dr. Houssay in recognition and appreciation of his contribution to medical science on nomination by a distinguished advisory committee. The association listed Dr. Houssay's most striking contribution to biology and medicine in the field of the pituitary gland, diabetes and carbohydrate metabolism.

FOREIGN

Flying Doctors.—Medical flights by the Flying Doctor Service in Australia "outback" last year covered 207,000 miles, an increase of more than 12,000 miles over the previous year. More than 5,000 patients, the service reports, were given medical advice by radio during 1946.

Fight Tuberculosis in Italy.—The United Nations Relief and Rehabilitation Administration joined Italian forces May 4 in a five year plan to combat a sharp increase in Italy's tuberculosis death rate. About 60,000 persons died in 1945, as compared with 33,226 in 1940, and it is estimated that 500,000 Italians need treatment at present. The plan will cost about $12,380,000 and will be financed from the sale of UNRRA imports in Italy. Reequipping ninety dispensaries, partly reequipping sixty-two more and providing 12,595 additional beds in eighty-eight hospitals are included in the program.

European Rheumatology Congress.—The first congress of this kind will be held at Copenhagen and Aarhus, Denmark, September 4-8. It is being sponsored by the International League Against Rheumatism. The scientific program beginning September 5 includes the discussion of etiology and pathogenesis of rheumatic fever and rheumatoid arthritis, with a special view to streptococci as the source of the disease; discussion on the treatment of rheumatoid arthritis, particularly gold treatment and other chemotherapy; the social importance of the rheumatic diseases, and biochematological problems of rheumatology. A two day sightseeing tour through Denmark has also been planned.

CORRECTIONS

American Psychiatric Association.—The second line of the item "Special Society Elections" in THE JOURNAL, June 14, page 621, should read the American Psychiatric Association instead of the American Pediatric Association.

Foreign Visitor.—Dr. Henry Makower (THE JOURNAL, May 10, p. 199) is chief assistant of the Institute of Medical Microbiology at the University of Wroclaw, Wroclaw, Poland, rather than of the University of Warsaw.

Date of Postgraduate Course.—The Columbia University course at Roosevelt Hospital "Recent Advances in Allergy," listed in Postgraduate Courses for Veterans and Civilian Physicians in THE JOURNAL, June 14, page 626, will be given November 3-8 instead of November 10-15 as listed.

Marriages

MERCER BRANNON SELL JR., Dallas, Ga. to Miss Ethel Elizabeth Smith of High Point, N. C., in Augusta, Ga., Dec. 27, 1946.

ROBERT BENTHAM SIMONS JR., Charleston, S. C., to Miss Sara Elizabeth Holden in Detroit Nov. 16, 1946.

HAROLD W. SPIES, Washington, D. C., to Miss Sadie Frances Compton of Johnson City, Tenn., January 30.

AMADEO B. SAELI, Savannah, N. Y., to Miss Ollie B. Hall of Sylva, N. C., in Salt Lake City February 15.

Deaths

Eben Elliot Smith ⊕ Medical Director, Captain, U. S. Navy, retired, Daytona Beach, Fla.; born near Dillsboro, Ind., July 12, 1891; Johns Hopkins University School of Medicine, Baltimore, 1917; fellow of the American College of Physicians; entered the U. S. Navy in 1917; during World War I served as medical officer at air stations in Ireland, on a destroyer and on a troop transport; on his return to this country assigned to the Naval Medical School as instructor in pathology; at various times served at Brooklyn Naval Hospital as clinical pathologist and ward officer, with the U. S. Marine Expeditionary Forces in Santo Domingo, on the U. S. S. *Saratoga* as a flight surgeon, at the Naval Air Station at San Diego, on the U. S. S. *Mississippi* as senior medical officer, in the Bureau of Medicine and Surgery as officer in charge of the division of publication and became editor of the *Naval Medical Bulletin*, and at the Naval Air Station, Jacksonville, Fla.; member of the Association of Military Surgeons of the United States, retired Oct. 1, 1945 for physical disability incurred in line of duty; died, June 16, 1946, aged 54, of coronary thrombosis.

Clyde Dale Blake, Hays, Kan.; born in Johnsonville, Ill., March 22, 1878; Kansas Medical College, Medical Department of Washburn College, Topeka, 1903; past president of the Kansas Medical Society; member and past president of the Central Kansas Medical Society; a charter member of the Golden Belt Medical Society; member of the American Medical Association, American Cancer Society and the Radiological Society of North America; fellow of the American College of Surgeons; member of the board of health; member of the founders group of the American Board of Surgery; served in the medical corps of the U. S. Army during World War I; captain, medical reserve corps, not on active duty; vice president of the board of directors of the First National Bank; a member and past president of the Rotary Club and past president of the chamber of commerce; formerly director of the state chamber of commerce; surgeon for the Union Pacific Railroad; chief of staff of the Hadley Memorial Hospital, where he died March 30, aged 69, of hypernephroma.

James Taft Pilcher ⊕ Brooklyn; born in Brooklyn on March 31, 1880; Columbia University College of Physicians and Surgeons, New York, 1904; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; member of the American Gastro-Enterological Association; served in the medical corps of the U. S. Army in France, a commanding officer of the 108th Field Hospital, holding the rank of major during World War I and for his services overseas received the Distinguished Service Medal; formerly a fellow in medicine at the Mayo Clinic in Rochester, Minn.; attending surgeon, Unity and Brooklyn State hospitals; consulting surgeon, Wyckoff Heights and Evangelical Deaconess hospitals in Brooklyn, Eastern Long Island Hospital in Greenport and the Jersey City Medical Center in Jersey City; managing editor of the *Annals of Surgery*; died in the Brooklyn Hospital April 6, aged 67, of angina pectoris.

Irvin Dilling Metzger, Pittsburgh; born in New Enterprise, Pa., April 12, 1873; Hahnemann Medical College and Hospital, Philadelphia, 1904; studied at the University of Vienna and in London, 1913-1914; served as chairman and president of the state board of medical education and licensure; for many years inspector of medical schools and hospitals; president of the Federation of State Medical Boards of the United States, 1935-1936; past president of the American Institute of Homeopathy; superintendent of public schools in Hollidaysburg, Pa., from 1895 to 1900; served during World War I; received honorary degrees from the Hahnemann Medical College of Philadelphia, Juanita College in Huntingdon, Pa., and the University of Pittsburgh; on the staff of the Shadyside Hospital, where he died April 1, aged 73, of pneumonia and leukemia.

Christian J. Amble ⊕ Albuquerque, N. M.; Illinois Medical College, Chicago, 1903; served as first treasurer of Torrance County; for three terms health officer of Torrance County; member of the Fourteenth Legislative Assembly, holding membership on various important committees; died recently, aged 79, of coronary thrombosis.

Rogers Coke ⊕ Marshall, Texas; University of Texas School of Medicine, Galveston, 1899; past president of the Harrison County Medical Society and of the Northeast Texas District Medical Society; fellow of the American College of Surgeons; regional chairman of the Selective Service Medical Advisory Board during World War II; chairman of the board of Kahn Memorial Hospital for many years; died February 11, aged 70, of cerebral hemorrhage.

Philip Patrick Crimmins, Brockton, Mass.; Baltimore Medical College, 1907; served during World War I; formerly affiliated with the U. S. Public Health Service reserve and various Veterans Administration hospitals; died February 27, aged 62, of coronary thrombosis.

Benjamin Franklin DeVore, Oakland, Ore.; Jefferson Medical College of Philadelphia, 1907; served during World War I; died in Eugene in February, aged 70, of coronary sclerosis.

Charles Elton Duffy ⊕ Parishville, N. Y.; University of Vermont College of Medicine, Burlington, 1896; died February 11, aged 76, of aneurysm of the abdominal aorta and arteriosclerosis.

Louis Martin Edens, Cabool, Mo.; University Medical College of Kansas City, 1907; member of the American Medical Association; died in St. Louis February 10, aged 61, of carcinoma of the larynx.

Morris Friedson ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1910; specialist certified by the American Board of Pediatrics; member of the New York Academy of Medicine; formerly on the faculty of his alma mater; on the staffs of the Beth David, Manhattan General and Gouverneur hospitals; formerly on the staffs of St. Mark's Hospital and the New York Nursery and Child Hospital; died March 17, aged 65, of heart disease.

Henry M. Hammond, Bergholz, Ohio; Baltimore Medical College, 1893; died February 9, aged 78, of angina pectoris.

Milton Mackey Osmun, Audubon, N. J.; Jefferson Medical College of Philadelphia, 1894; died in the Camden County General Hospital in Lakeland February 16, aged 88, of myocarditis and hypertension.

Argy Nicholas Padrous, Detroit; Marquette University School of Medicine, Milwaukee, 1943; began active duty as a first lieutenant in the medical corps, Army of the United States, in January 1944; released from the service with the rank of captain in September 1946; interned at the Grace Hospital, where he died February 14, aged 35, of acute glomerular nephritis and hypertension.

Jesse Ross Porter, Davenport, Iowa; Drake University Medical Department, Des Moines, 1897; died March 26, aged 77, of heart disease.

William Potter, Mason City, Iowa; Trinity Medical College, Toronto, Ont., Canada, 1892; died February 25, aged 80, of cerebral hemorrhage.

Wallace Preble, Cambridge, Mass.; Harvard Medical School, Boston, 1883; member of the American Medical Association; died February 22, aged 89, of cerebral thrombosis.

Willard De Forest Preston, Attica, N. Y.; University of Vermont College of Medicine, Burlington, 1899; member of the American Medical Association; veteran of the Spanish-American War and World War I; health officer of the consolidated health district of Attica since 1921; affiliated with St. Jerome and the Genesee Memorial hospitals in Batavia and the Wyoming County Community Hospital in Warsaw; surgeon for the Erie Railroad; died February 28, aged 69, of heart disease.

Mark Wyman Richardson ⊕ Boston; Harvard Medical School, Boston, 1894; member of the Association of American Physicians; formerly secretary of the state board of health; died February 12, aged 79, of coronary heart disease.

George W. Tape, Shell Beach, Calif.; Detroit College of Medicine, 1889; died March 11, aged 81, of cerebral hemorrhage and arteriosclerosis.

Cornelius Carl Weber ⊕ Philadelphia; Georgetown University School of Medicine, Washington, D. C., 1936; diplomate of the National Board of Medical Examiners; interned at the Misericordia Hospital, where he was a member of the staff; formerly member of the staff of the Jefferson Hospital and associated with the Abington (Pa.) Hospital, Temple University and St. Mary's hospitals; died March 12, aged 35.

George W. Wood, Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; associate in gynecology at his alma mater; fellow of the American College of Surgeons; member of the American Medical Association; served during World War I; on the staffs of the Methodist, City and St. Vincent's hospitals; died March 16, aged 67, of coronary occlusion.

Nelson A. Wright Sr. ⊕ Manito, Ill.; Missouri Medical College, St. Louis, 1899; past president of the Mason County Medical Society; died in the Methodist Hospital in Peoria March 25, aged 72, of uremia following a prostatectomy.

The British Journal of Nutrition

The Cambridge University Press announces the publication shortly, for the Nutrition Society, of a new quarterly, the *British Journal of Nutrition*. It will be devoted to reports of original work in all branches of nutrition and will incorporate the *Proceedings of the Nutrition Society*, which at present are published separately. The editorial board will consist of S. K. Kon (chairman), D. P. Cuthbertson, J. N. Davidson, R. C. Garry, G. Graham, J. Hammond, E. M. M. Hume, I. Leitch, W. C. Miller, F. Yates, B. S. Platt and J. A. B. Smith. Subscription rates for nonmembers of the Nutrition Society are $12.50 per volume of four quarterly parts. Separate parts will cost $4. Subscriptions should be addressed to the Cambridge University Press, 200 Euston Road, London, N. W. 1. Papers for publication and letters on editorial matters should be sent to Dr. S. K. Kon, *British Journal of Nutrition*, National Institute for Research in Dairying, Shinfield, near Reading, Berks, England. Information about the Nutrition Society may be had from the secretary at the same address.

Bicentenary of the Rotunda Hospital, Dublin

The bicentenary of the Rotunda Hospital, Dublin, the oldest obstetric hospital in the British Isles, will be held from July 7 to 11. Visitors will attend from all parts of the world. The opening session will be on the history of midwifery. The discussion will be introduced by Dr. T. P. C. Kirkpatrick and Dr. G. W. Kosmack, editor of the *American Journal of Obstetrics and Gynecology*. Other subjects for discussion are puerperal sepsis, eclampsia, shock in obstetrics, sterility and fetal and neonatal mortality. Visiting speakers will include Professor H. J. Stander of Cornell University, Professor F. C. Irving of Harvard, Professor Subodh Mitra of Calcutta, Dr. J. I. Hofbauer of Cincinnati, Professor H. L. Sheehan of Liverpool, Professor W. A. Scott of Toronto, Professor Henri Bedrine Lisle, Dr. J. V. O'Sullivan of London, Dr. Isidore Rubin of New York, Professor Axel Westman of Stockholm, Professor Bernard Zondek of Jerusalem, Dr. Peter Bishop of London, Professor J. S. Browne of Montreal, Professor Ebbe Brandstrup of Copenhagen, Professor F. J. Browne of London and Professor Dugald Baird of Aberdeen. Further particulars as regards the congress can be obtained from the secretary, 36, College Green, Dublin.

Acute Pancreatitis with Subcutaneous Fat Necrosis

While fat necrosis due to acute pancreatitis is commonly seen within the abdomen, where it affects the mesentery, omentum, pancreas and peritoneum, it is rare outside the abdomen except in the extraperitoneal fat. It has been observed in more distant regions—the mediastinum, pleura, pericardium, marrow of the long bones and periarticular fat. But, except when experimentally produced in animals, necrosis of subcutaneous fat seems to have been first reported in the *British Journal of Surgery* by Hugh Blauvelt. A married woman aged 41 was admitted to the hospital on Oct. 27, 1939 complaining of epigastric pain of two days' duration. Nausea and vomiting occurred the day before admission. She suffered from constipation, and micturition was difficult. The temperature was 99.6 F., the pulse 120 and the respiratory rate 24. While the abdomen was not distended, there were generalized tenderness and rigidity, more especially over the gallblader. The diagnosis lay between acute cholecystitis and acute pancreatitis. Next day many red areas, resembling erythema nodosum, appeared on the arms and legs. On October 29 laparotomy was decided on. The incision revealed necrosis of the extraperitoneal fat, and the abdomen was not opened. Excision of a portion of one of the superficial lesions on a leg revealed typical fat necrosis. The superficial areas of fat necrosis were confined to the arms, legs and buttocks excepting two on the back. They varied in size from a pin prick to a patch 2 inches or more in diameter. The urinary diastase amounted to 2,400 units in twenty-four hours. The blood sugar was 90 mg. per hundred cubic centimeters. Loewi's mydriatic reaction was positive. X-rays showed signs of gallstones. Recovery was slow. When examined seven months after the onset all external signs of fat necrosis had disappeared except a few rose colored areas on the thighs. On Aug. 8, 1940 two small stones and a chronically inflamed gallbladder were removed. On August 10 she became comatose, and death ensued in twenty-four hours. The blood urea before death was 200 mg. per hundred cubic centimeters. At the necropsy the bile ducts and pancreas were found normal and there was no evidence of recent or old fat necrosis. The kidneys were small and granular, and death was attributed to chronic nephritis.

The lesions so frequently found in the peritoneum, mesentery and pancreas itself in acute pancreatitis are attributed to the direct spread of the liberated ferment. When extraperitoneal fat, pleura, pericardium and mediastinum are affected, the lipase is said to travel by the lymphatics. Necrotic lesions in the bone marrow and periarticular tissues have been attributed to pancreatic emboli travelling by the blood stream. This would best account for the subcutaneous lesions that were observed.

SÃO PAULO, May 3, 1947

The Stoneless Gallbladder

Dr. João Montenegro says that, as diagnostic methods improve, fewer patients with chronic cholecystitis without stones are operated on. Indeed, clinical cholecystitis without stones is becoming a rare disease. Most of the symptoms ascribed to it in the past were due to intestinal dyskinesia caused by food intolerance, and sometimes to dyskinesia of Oddi's sphincter having the same cause. The hepatic flexure of the colon and the duodenum are the main mystifiers. Intestinal dyskinesia produces erratic spontaneous pains with predilection for the duodenocholecysticocolonic (hepatic flexure) and appendicular areas, while elecited pains are encountered generally in more than one spot, or the whole abdomen may be tender but without muscular rigidity. Proper dieting, rest and supporting measures will relieve them. This intestinal dyskinesia, also called irritable colon, has led to cholecystectomies on normal gallbladders with a fair percentage of cures resulting from postoperative rest, dieting, muscular relaxation and ease of mind. On the other hand, well indicated cholecystectomies have failed to cure patients mainly because of the coexistence of the bowel dyskinesia. The diseased gallbladder is removed and the symptoms caused by it are allayed but the trouble caused by the dyskinesia persists. To obtain highly probable, complete cures one must be reasonably sure that there is not a coexistence of diseases. Poor results from other diagnostic errors and sequelae represent a small percentage in the series of cholecystectomies. Pathologists are urged to refrain from the diagnosis of cholecystitis in specimens that do not show clearcut evidences of inflammation, as suggested by Foss, because such a diagnosis encourages cholecystectomies on normal gallbladders. They should avoid meaningless expressions as chronic catarrhal cholecystitis; instead of that, more anatomopathologic expressions might be employed, such as exudative and proliferative cholecystitis.

Correspondence

PROLONGED REACTION TO BENADRYL

To the Editor:—In a clinical note entitled "Prolonged Reaction to Benadryl" (The Journal, February 8, p. 393) appeared the statement "Treatment was not given, but intravenous histamine was elected as the treatment of choice if the condition failed to improve." This rather innocuous remark provoked the following criticisms from Dr. Norman A. David and Dr. Norman W. Karr of the department of pharmacology, University of Oregon Medical School:

1. Fundamental principles were overlooked.
2. Procedures suggested in The Journal may be adapted in toto by the general practitioner too busy to investigate further.
3. In a case of shocklike reaction to benadryl, such as that reported by other authors in the same issue of The Journal, histamine could aggravate the condition with possible fatal outcome.
4. *Histamine could be harmful in a case such as the one* reported.
5. The authors' suggestion, which may have been justified in their case, should have been accompanied with a strong word of caution.
6. The radical treatment proposed. . . .
7. The use of intravenous histamine has no theoretical justification in most reactions to benadryl.

The objections to the contemplated use of the drug were on the following basis:

1. "Drugs seldom react on one mechanism or system. It is probable that most of the toxic reactions to benadryl involve mechanisms entirely distinct from its histamine activity."
2. "Histamine causes increased permeability of blood vessels —a picture closely resembling clinical shock."

Since the mechanism of the action of benadryl itself is unknown, much less the toxic reactions, the first objection is purely speculative.

The second statement is valid, or at least the first half of the statement is valid. As a matter of fact, this sentence (half sentence that is) is the only statement in the entire communication (with the exception of the sentence pertaining to drugs acting on more than one system), that can be substantiated by scientific proof. If this was the basis of the charge of overlooking fundamental principles, it would appear to be logical (but not excusable) since histamine causes capillary dilatation and increased permeability and would therefore appear to be theoretically contraindicated when these factors are already present in conditions such as drug reactions. Furthermore, histamine exposure can cause anaphylactic shock in some lower animals. Oddly enough, however, clinical evidence refutes the theoretical contraindications. Intravenous histamine has been successfully used for treatment of many allergies including that of penicillin urticaria, in which increased capillary permeability and dilatation are strongly in evidence. Bayard T. Horton, chief of the research division at the Mayo Foundation, in a paper read before the Southwest Allergy Forum in April 1946, stated that he and his co-workers had given thousands on thousands of injections of intravenous histamine in the aforementioned types of cases, without reaction, with good results, and considered it a safe drug. It is assumed that any one using histamine or any other medication will use proper dilution, technic of administration and precautions.

The reasons histamine was considered for use in the case under discussion are that:

1. It is the accepted antagonist of benadryl.
2. It has been successfully used in dissipating allergic edemas including those of drug reactions. Perineural edema was thought to *be responsible for the neuritic symptoms in the* case reported.
3. The drug was considered safe for the type of case under discussion.

It should be further pointed out that the use of histamine was not recommended to others. It was simply considered the treatment most likely to be of help in the one particular case under discussion—no other. It was to be used only if more conservative treatment failed. It was not used.

It is felt that a dissertation on indications, limitations and possible dangers of a drug that was not used, in a case report, would have encroached on the technic of Colonel Stoopnagle and Budd.

It is further felt that the criticisms were unwarranted, unsubstantiated and, most amazing of all, directed against conditions foreign to the case in question and at a drug which was not used.

Sam Schwartzberg, M.D., San Antonio, Texas.

THE GENERAL PRACTITIONER IN THE HOSPITAL ORGANIZATION

To the Editor:—Dr. M. H. Miller's article in The Journal, May 3, Page 15, creates a desire to express the opinion that parallel discussion is necessary in the promotion of policy matters. Our constant problem, personal, political, social and economic, is to choose between being militant and being decent. We may do business by meeting the buyer or the seller in a private personal deal and appealing to the law, to be made whole, in case of injury, or through a third person armed with a directive which converts the transaction into a public or communal matter. Our constant choice is between socialization and civilization. If we choose to be militant we must be controlled by directives through a third party; if we choose to be decent we can live in freedom under the law; there is no middle ground.

A militant person joins a machine to force another to serve him. He looks on himself as a cog in a wheel and limits his activities to assigned duties in socialization at the grasping collectivistic level of the ego. A decent person looks on himself as the wheel and is willing to serve another individual by all the talent and skill he possesses in civilization at the economical altruistic level of the super ego.

Harvey Cushing would probably not have established single service trade school training in this country if he had foreseen that the medical profession would regress to medieval authoritarianism as a result. We must not mistake militancy for sincerity or allow the boorish boasts of bound boys to pass for professional competence when it is merely a defense mechanism used to cover their lack of integrative ability.

Mount Carmel Mercy Hospital is to be congratulated on maintaining a form of civilization far beyond the achievement of the majority of our hospitals that have been bound to a single standardization. They too have failed to separate the men from the boys by instituting "the table of organization" which is the wheel on which the single service cogs are bound as opposed to allowing a free medical market. The tradition of voluntary hospitals is to treat the doctor and the patient as guests of the hospital at all times. They have succeeded in introducing the socializing third party which continues to price a larger number of people out of the hospital market. This process can only continue to complete nationalization. Organized medicine must rehabilitate to civilization as the Supreme Court of the United States has in reaffirming "the doctrine of civilization" in the Beelo case.

The multiple service doctor is the sensitive idealistic adult who looks on himself as the wheel but who is willing to add an additional cog when the need arises. He is capable of operating the free medical market of civilization.

M. W. Stevens, M.D., *Portland, Ore.*

POSTGRADUATE COURSES FOR VETERAN AND CIVILIAN PHYSICIANS

Compiled by the Council on Medical Education and Hospitals for Period July 1, 1947 to Jan. 15, 1948

(Concluded from page 634)

Medical schools, hospitals, state medical societies and other medical educational institutions and organizations are providing the Council with a growing body of information on courses designed primarily to meet the needs of returning medical officers. These have been incorporated into the lists on these pages. They are not specifically designated for veterans, since most if not all of them may also be open to interested civilian physicians. Furthermore, all courses listed which were not designed primarily for physician veterans are also open to qualified returning medical officers.

Note that each course is listed only once, without cross indexing, so that in some instances a prospective student should look under more than one heading for a desired course.

University of Pennsylvania Graduate School of Medicine, 237 Medical Laboratories, Philadelphia 4	Neurology, Psychiatry (Basic Studies)	8 months, full time, October 1947-May 1948	800 00
At Affiliated Institutions	Clinicobiologic Neurology and Psychiatry [2]	10 weeks, full time	300 00
University of Texas Medical Branch 912 Avenue B, Galveston	Technical Procedure of the Neurological Examination	Arranged	Not given

NEUROSURGERY

Institution	Title of Course	School and Course	Registration Fee and/or Tuition
University of Wisconsin Medical School, 418 N Randall St, Madison	Neurosurgery for Specialists [2]	2 6 months, arranged	per month 100 00

NUTRITION

Institution	Title of Course	School and Course	Registration Fee and/or Tuition
New York Medical College, Flower and Fifth Avenue Hospitals, 20 E 106th St, New York	Nutrition	1 month, arranged	150 00
University of North Carolina School of Medicine Chapel Hill	Nutrition	Not given, arranged	25 00
Duke University School of Medicine, Durham, N C	Nutrition	3 months or longer, full time, arranged	per month 50 00

OBSTETRICS AND GYNECOLOGY

Institution	Title of Course	School and Course	Registration Fee and/or Tuition
Alabama State Health Department and Jefferson County Health Department, Birmingham At Slossfield Maternity Center	Refresher Course in Obstetrics and Gynecology	3 days, September 1947	15 00
	Institute for Negro Physicians (Obstetrics)	[illegible] days, full time, September 1947	15 00
College of Medical Evangelists Graduate School of Medicine, Boyle and Michigan Ave, Los Angeles	Basic Sciences in Obstetrics and Gynecology	33 weeks, full time, October 1, 1947 June 11, 1948	500 00 plus nominal fees
University of Southern California School of Medicine, 1200 N State St, Los Angeles 33 At Los Angeles City Health Department Maternity Division	Clinical Obstetrics (Course 757)	12 weeks, part time, special arrangement	50 00
At Los Angeles County Hospital	Obstetrics and Gynecology (Course 753)	2 weeks, full time, October 1947	100 00
University of California Medical School, San Francisco 22 At University of California Medical Center	Gynecology and Obstetrics Pathology-Smear, Technique Cancer of Uterus, Stomach Urinary Tract Lungs	2 weeks, full time, Aug 4 15, 1947	full course 115 00 mornings 80 00 afternoons 65 00
	Obstetrics and Gynecology	5 days, full time, September 1 5, 1947	35 00
Chicago Maternity Center, 1336 Newberry Ave Chicago	Assistant-residency in Obstetrics	4 6 months, continuously	None
Cook County Graduate School of Medicine, 427 S Honore St, Chicago	Obstetrics	2 weeks, full time, September 8, 1947	150 00
	Operative and Office Gynecology	2 weeks, full time, September 22, 1947	150 00
	Personal Course in Gynecological Surgery	4 weeks, part time, July 10, 1947	80 00
	Personal Course in Gynecological Surgery	4 weeks, part time, September 4, 1947	80 00
	Practical and Didactic Course in Office Gynecology	4 weeks, part time, July 9, 1947	80 00
	Practical and Didactic Course in Office Gynecology	*4 weeks, part time, September 3, 1947*	*80 00*
University of Kansas School of Medicine, 39th St and Rainbow Blvd, Kansas City	Obstetrics and Gynecology	4 days, November 17 20, 1947	20 00
University of Maryland School of Medicine, Lombard and Greene St, Baltimore	Review of Gynecology, Oncology and Female Urology	10 weeks, full time, arranged	125 00
	Review Obstetrics and Gynecology	6 weeks, full time, arranged	150 00
Long Island College of Medicine and Medical Society County of Kings, 1313 Bedford Ave, Brooklyn 16	Complications of Pregnancy	8 sessions, twice a week, October 7, 1947	20 00
	Prenatal Care	8 sessions, once a week, October 16, 1947	20 00
Columbia University College of Physicians and Surgeons, 630 W 168th St, New York 32	Observation Course in Obstetrics	1 month, full time, 1st of every month	100 00
At Margaret Hague Maternity Hospital, Jersey City, N J	Obstetrics—Internship Training	3 months, full time, 1st of every month except November and December	850 00
At Mount Sinai Hospital	Recent Advances in Gynecology	6 days, full time, December 15-20, 1947	65 00
New York Polyclinic Medical School and Hospital, 341-353 W 50th St, New York	Clinical and Operative (cadaver) Gynecology	6 weeks, arranged	175 00
	Combined Obstetrics and Gynecology	2 months, full time, October 1, 1947	250 00
At Beth Israel Hospital	Gynecology	16 weeks, part time, August 1947	250 00
	Gynecology	16 weeks, part time, December 1947	250 00
At Lenox Hill Hospital	Histopathology for Gynecologists	5 weeks, part time, September 30, 1947	50 00
	Histopathology for Gynecologists	5 weeks, part time, January 6, 1948	50 00
New York Post-Graduate Medical School, 303 E 20th St, New York 3	Gynecology—Diagnosis and Office Treatment	15 sessions, part time, September 29 October 31, 1947	75 00
	Gynecology—Diagnosis and Office Treatment	15 sessions, part time, November 10 December 12, 1947	75 00
	Gynecology, Diagnosis and Office Treatment	10 sessions, part time, December 1 22, 1947	50 00
	Gynecological Pathology (Restricted to Gynecologists and Pathologists) [2]	16 weeks, part time, September 24, 1947-January 21, 1948	100 00
	Gynecological Pathology (Restricted to Gynecologists and Pathologists) [2]	16 weeks, part time, January 6 February 26, 1948	100 00
	Seminar in Gynecology	2 months, full time, October 1-November 29, 1947	300 00
	Surgical Anatomy as Applied to Operative Gynecology (Cadaver) Limited to Surgeons [2]	12 sessions, part time, arranged	200 00
Duke University School of Medicine, Durham, N C	Obstetrics and Gynecology	3 months or longer, full time, arranged	per month 50 00
University of Cincinnati College of Medicine, Eden and Bethesda Ave, Cincinnati, Ohio	Seminar in Obstetrics for the General Physician	1 month, twice a week, October 1947	15 00
Oklahoma State Medical Association Postgraduate Committee, 210-212 Plaza Court, Oklahoma City 3 At Principal towns and cities in State	Gynecology	10 weeks, one night a week, not given	15 00
Oregon State Medical Society and Oregon State Board of Health, Portland	Obstetrics Refresher Course	Arranged, tentatively Fall 1947	Not given
University of Oregon Medical School, 3181 S W Marquam Hill Road, Portland 1	Gynecology	5 days, full time, October 27 31, 1947	50 00
Hahnemann Medical College and Hospital of Philadelphia, 235 N 15th St, Philadelphia	Obstetrics	*2 months, full time, July 1, 1947* January 15, 1948	200 00
University of Pennsylvania Graduate School of Medicine, 237 Medical Laboratories, Philadelphia 4	Gynecology, Obstetrics (Basic Studies)	8 months, full time, October 1947 May 1948	800 00

---

[1] Special contract to War Department

[2] Specialists only

[3] Stipends up to a maximum of $250 00 per month are available if certain qualifications can be met

[4] Half fee to physicians in service

[5] Followed by 12 months in hospital administrative internship

[6] Training given in various institutions throughout country Applicant must make his own arrangement with institution

[7] Stipend paid on per diem basis

[8] In each teaching district—covering the state in 2 years

[9] Pre-requisite—Course 730

[10] Evening seminars to be announced during course

[11] Fellows and Jr candidates

[12] Including dinners and luncheons

[13] Write for schedule to Committee on Graduate Education, 230 State St, Harrisburg, Pa

[14] Includes meals

[15] Free to physicians on active duty at Cook County Psychopathic Hospital

[16] Full-time employees of the Illinois Department of Public Welfare pay no fee

[17] Restricted to physician candidates of the Topeka Institute for Psychoanalysis

[18] Candidates in training only

[19] $5 00 per session paid to physician in training by State Department of Health

[20] Or equivalent if taken on part time basis

[21] Especially for candidates for American Board of Surgery

[22] No extra charge for longer stay

[23] Stipend (including travel) and tuition fee (when there is such) paid for by the department

[24] Paid by State Health Dept, also stipend paid during training period

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Revocation of License for Unlawful Advertising.—This was a proceeding to revoke the license of the defendant to practice dentistry. From a judgment of the district court setting aside a revocation order entered by the state board of dental examiners, the board appealed to the Supreme Court of Kansas.

Early in April 1941 the defendant, then practicing dentistry in Kansas City, began running advertisements in the Kansas City *Kansan* and the *Shopper,* newspapers in general circulation in Kansas City, of a kind which violated the provisions of the dental practice act, the Code of Ethics of the American Dental Association and the rules of the board of dental examiners. The secretary of the board accordingly wrote the defendant, calling attention to that fact. The defendant replied, expressing his desire to conduct his business in an ethical way and asking for specific information as to in what way he was not doing so. Following receipt of this letter, the attorney for the board called on the defendant and made a full explanation to him of the objectionable nature of his advertisements, furnished him copies of the Code of Ethics and the board's rules and referred him to the pertinent statute. Later the board's attorney also wrote to the defendant, referred to the interview and again detailed the matters which had been discussed. The defendant referred this letter to a lawyer, who requested and received an interview with the attorney for the board. At the interview the entire matter was again gone over, with the ultimate result that defendant's attorney took the position that, while what the defendant was doing was contrary to the rules of the board, the board had no authority to make such rules and hence defendant was not engaged in unethical or dishonorable conduct. A complaint was filed before the board on Nov. 15, 1941 and a copy of it sent to the defendant by registered mail. At the date set for a hearing, the board heard the arguments of all the parties and concluded that the complaint should be further investigated. [At this point the defendant appealed to the Supreme Court on the right of the board to conduct the hearing on the complaint. The defendant lost (*Bohl* v. *Teall,* 155 Kan. 505, 126 P (2d) 216.)] The matter was set for hearing on Aug. 10, 1942. At that time the defendant made an offer to cease the objectionable advertising if the complaint was dismissed. A hearing respecting the good faith of the defendant in making that offer was conducted, and the board took the matter under advisement pending the final hearing, at which the board went fully into the complaint and the evidence and entered an order revoking the defendant's license. [At this point the defendant obtained an injunction restraining the board from enforcing its revocation order. Again the matter was taken to the Supreme Court (*Bohl* v. *Teal,* 157 Kan. 239, 139 P (2d) 418), which held that the defendant's proper remedy was by appeal of the board's order and not by an independent action to restrain the board from enforcing its order.]

From our examination of the record, said the Supreme Court, we find nothing which justified the trial court in finding that the order of the board was unreasonable, arbitrary, oppressive and illegal. The board gave the defendant as fair treatment and consideration as any one could expect. The testimony before the board justified its findings, and the Dental Practice Act authorized the board to conduct such a hearing and to make the order revoking the license if the evidence disclosed that it should be done. Continuing, the Supreme Court pointed out that a member of a profession which has high ethical standards in order that its members may have the high standing in the community which their education and training justify, and which standards are beneficial to the health and welfare of those whom they serve, should conform to them. Apparently, said the court, the defendant violated these standards, and when his attention was called to the matter he professed ignorance. With reasonable promptness he was informed in a personal interview and in writing by the board's attorney. Defendant blocked a full inquiry, the court continued, but enough did get into the record to tend to show conduct on the part of the defendant which the board might regard as being professionally dishonorable. It is not for this court, nor was it for the trial court, to pass upon the evidence before the board as to whether or not it established grounds for revoking the defendant's license. The court concluded that it had no authority to substitute its judgment for that of the board.

The court also held that legal questions relating to procedure of this kind are well established by former decisions of the Kansas Supreme Court. Council for the defendant cited *Capland* v. *Board of Dental Examiners,* a prior Kansas case, as controlling. But in that case, the Supreme Court pointed out, the board had not made the rules authorized by statute. In this case the rules had been adopted by the board prior to any of the objectionable conduct of the defendant, a fact of which he either knew or was promptly informed before any proceedings were started. On behalf of defendant, it was also argued that because some general definitions of dishonorable conduct were stated in the Capland case the board had no authority to embody in its rules a definition of dishonorable conduct. The point is not well taken, said the Supreme Court. The general definitions of dishonorable conduct quoted in the opinion did not preclude the board from considering its own profession and making rules defining dishonorable conduct as being that which was opposed to the long standing Codes of Ethics of the profession.

Accordingly, the judgment of the trial court was reversed with directions to affirm the order of the board revoking the defendant's license to practice dentistry in Kansas.—*State Board of Dental Examiners v. Bohl, 174 P. (2d) 998 (Kansas, 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal June 14, page 635.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* September. *Part III.* Various centers, June. Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Part II. *Oral.* Cleveland. Oct. 5-11. Sec., Dr. P. M. Wood, 131 Riverside Dr., New York 24.

American Board of Dermatology and Syphilology: *Part I. Oral.* Chicago, Oct. 24-26. Final date for filing application is Aug. 1. *Part II. Written.* Various centers, Sept. 15. Sec., Dr. G. M. Lewis, 66 E. 66th St., New York 21.

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Feb. 1. Sec., Dr. W. J. German, 310 Cedar St., New Haven, Conn.

American Board of Ophthalmology: Chicago, October 6-12. Sec., Dr. S. Judd Beach, 704 Congress St., Portland, Me.

American Board of Orthopaedic Surgery: Part II. Chicago, Jan. 22-23. Final date for filing applications is Sept. 15, 1947. Sec., Col. F. M. McKeever, 1136 W. Sixth St., Los Angeles 14.

American Board of Otolaryngology: Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pathology: Chicago, Oct. 24-25. Final date for filing application is Sept. 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kingshighway, St. Louis 10.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants. Applications should be sent to Sec., Dr. Louis T. Byars, 508 N. Grand Blvd., St. Louis.

American Board of Psychiatry and Neurology: New York, December. Final date for filing application is Sept. 15. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S. W., Rochester, Minn.

American Board of Radiology: *Oral.* Boston, Nov. 26-30. Final date for filing application is Aug. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Avenue, S. W., Rochester, Minn.

American Board of Surgery: *Examination. Part I. Written.* Various centers, Oct. *29. Final date for filing application* is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, February. Final date for filing application is *Nov. 1: Sec., Dr. Harry Culver,* 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Basal Cell Epithelioma in Psoriatic Patch. A. G. Franks and J. L. Barner.—p. 375.
Treatment of Mycotic Infections by Inhibiting Respiration of Dermatophytes. F. A. Dolce and W. J. Nickerson.—p. 379.
Reactions in Treatment of Syphilis with Penicillin. S. Fromer.—p. 385.
*Undecylenic and Propionic Acids in Prevention and Treatment of Dermatophytosis. M. B. Sulzberger and A. Kanof.—p. 391.

Vitamin A in Acne Vulgaris.—Lynch and Cook studied the effects of vitamin A given orally in daily doses of 100,000 units to a group of university students with acne. The patients received no advice as to diet or hygiene, and no other treatment was given. There were 45 patients to whom vitamin A was given for a sufficient length of time (four or five months) to permit evaluation. A comparison of the results of vitamin A treatment with those obtained with nicotinic acid or other treatments reveals that vitamin A does not produce remarkable improvement in acne.

Undecylenic and Propionic Acids in Dermatophytosis.—Sulzberger and Kanof summarize the results of experiments performed under the direction of the Research Division of the Bureau of Medicine and Surgery of the United States Navy. The object of the experiments was to ascertain the efficacy of certain fatty acids and their salts in the prophylaxis and treatment of dermatophytosis. Nine agents were compared and are listed in approximately descending order of efficiency: 1. Undecylenic acid-undecylenate powder. 2. Diodoquin 5 per cent in talcum powder. 3. Vioform 1 to 3 per cent in talcum powder. 4. Calcium-zinc propionate powder. 5. Sodium propionate powder. 6. Foot powder U. S. N. 7. Boric acid-salicylic acid powder. 8. Talcum powder. 9. Thiourea 5 per cent in talcum powder. Undecylenic acid-undecylenate powder was slightly more effective than the boric acid-salicylic acid powder. Approximately one fourth of all the men studied and examined had clinical evidence of active fungous infection of the feet.

Occupational Therapy in Rheumatoid Arthritis. H. P. Wright.—p. 313.

Heart Catheterization in Congenital Heart Disease.—The report by Johnson and his associates is based on the study of 17 children with congenital heart disease in which this approach has been employed. The patients ranged in age from 19 months to 16 years. Of the 17 patients studied, 9 were considered to have interventricular septal defects in view of the information provided by catheterization. The authors regard the method of heart catheterization as a most useful adjunct in the investigation of congenital heart disease.

Glomus Tumor. W. H. Gerwig Jr.—p. 135.

Nondysenteric Amebiasis.—Perry thinks that amebiasis is generally thought of only in terms of amebic dysentery. He stresses the importance of the carrier state, in which the lesions are smaller and often microscopic. The organisms tend to grow in the cecum and the terminal ileum. The appendix is frequently involved and is often removed for so-called chronic appendicitis. No patient with so-called chronic appendicitis should have an appendectomy without first having adequate studies of the stools for amebas. Patients with nondysenteric amebiasis have a tender cecal area and a somewhat enlarged and palpable liver. There is need for a careful study of the feces whenever these signs are detected. The author has detected amebas in persons with rheumatoid arthritis and thinks that the lesions produced in the right colon by the ameba in the carrier or nondysenteric state are capable of providing a port of entry for pathogenic bacteria. He cites a case which illustrates the role amebiasis may play in rheumatic difficulties and how treatment of the amebiasis will counteract the rheumatic symptoms.

Portacaval Anastomosis.—Blakemore thinks that the principle of establishing portacaval shunts to effect a reduction of blood pressure in the portal system in cases of portal hypertension is a sound one, but in the first operations of this kind the anastomosis often became occluded by a thrombus. The difficulty of accurate placement of each stitch so necessary for a perfect intima to intima coaptation of the vein walls induced the author and Whipple to try a nonsuture technic employing vitallium tubes in the establishment of portacaval shunts. The nonsuture method of blood vessel anastomosis affords a broad intima to intima coaptation of the vessel walls without an intervening foreign body suture. The author illustrates the technic and discusses the indications for the anastomosis. The operation has been performed on 17 patients. In this group there were two postoperative deaths. In 6 patients the site of the portal obstruction was extrahepatic. Ten of the 11 remaining patients had portal cirrhosis. Sufficient time has elapsed since operation to have some follow-up significance in 8 cases of cirrhosis. In 1 of these with esophageal varices but no ascites there was a rise in total proteins and albumin following operation. In 2 other cases there was a slight rise in total proteins and albumin following operation, whereas in the remaining 5 cases there was a slight fall of these. Ascites disappeared following establishment of the portacaval shunts in spite of lowered proteins in 3 cases; this emphasizes the role of portal hypertension as a causative factor.

Androgen Control in Carcinoma of Prostate.—Herger and Sauer review the results obtained with endocrine therapy in 130 cases of prostatic cancer. They found that after initial benefit resurgent symptoms develop in the majority of the cases after variable periods of time. This indicates that endocrine therapy in its present form does not cure nor does it retard the disease indefinitely. Indiscriminate use of orchiectomy in patients with prostatic cancer is decried. Castration should be reserved for patients in whom immediate relief from pain is desired or patients in whom estrogen administration has lost its effectiveness. Estrogen administration given in cases of failures following castration is usually ineffective while failures occurring after exclusive estrogen therapy show fair response to subsequent castration. Androgen control therapy does not prevent formation of metastases in patients with apparently quiescent disease.

Gastric Resection for Carcinoma of Stomach: Kronlein Technic. A. B. Carney—p. 88.

Brucellosis in Children.—Russell reports observations on 141 children with tissue sensitivity to Brucella vaccine as manifested by a positive skin test. The search was suggested during the past two years by the letting down of the bars to raw dairy products due to rationing, and by the presentation by the parents of the occasional child with symptoms similar to their own and diagnosed as probable ambulant forms of brucellosis. In 123 of the 141 there was a definite history of fever, usually of the remittent type. Vague pains of the skeletal system, chiefly leg ache and backache, were present in 50 children, with headaches in 13. Forty-two children gave a history of vague gastrointestinal symptoms. Eighty-eight had a history of using raw or unpasteurized dairy products, including milk, cream and country butter. Associated conditions, although not necessarily due to brucellosis, may be connected with it when the protean character of its manifestations is taken into consideration. There were ocular and pulmonary manifestations, lymphadenopathy, skin lesions, spondylitis, joint manifestations and alopecia. Vaccine therapy was tried in children who showed no spontaneous improvement after one or two months. Great improvement was effected with vaccine in 9 patients, moderate improvement in 11, slight improvement in 8 and no improvement in 2. The blood sedimentation level has been found to be a valuable aid in following the activity of brucellosis infection. Russell suggests investigation of the use of Brucella prophylactic vaccine, perhaps as a combination with typhoid and paratyphoid, as tried by Kolmer.

Opinion Poll on Reactions to "The Lost Weekend."—p. 596.

B Vitamins and Voluntary Alcohol Consumption.—Brady and Westerfeld found that rats maintained with a diet containing all the known members of the yitamin B complex plus Wilson's liver fraction L did not consume alcohol in autoselection experiments. Rats consumed relatively large amounts of alcohol voluntarily when fed a diet deficient in members of the vitamin B complex. Once the alcohol intake became elevated on a deficient diet it could not be restored permanently to low levels by feeding a "complete" diet; inclusion of missing factors in the diet usually brought about a temporary decrease in alcohol consumption.

Insulin Subshock as Detoxicant in Alcoholic Intoxication.—Insulin ranging from small amounts to subshock dosages was administered by Thimann and Peltason in the therapy of uncomplicated acute alcoholic intoxication and acute alcoholic psychoses to 120 patients. In the alcoholic psychoses 10 to 20 units of insulin given simultaneously with dextrose proved the method of choice. Uncomplicated acute alcoholic intoxication responded best to subshock doses of insulin. The duration of the sobering up process was reduced in most cases from the two to four days required under previous technic to one day and often to only a few hours. Patients prefer this technic to the conventional method of substituting paralydehyde or chloral for alcohol. The staff was of the impression that in 20 per cent of these 120 patients the insulin method had no advantage over the conventional method. In the remaining 80 per cent the insulin technic proved to be superior.

Ligation of the Inferior Vena Cava in Thromboembolism.—Thebaut and Ward emphasize the importance of thrombosis in the deep veins of the lower extremities and discuss its surgical management once pulmonary infarction has occurred. In 34 of 36 patients ligation of the inferior vena cava was performed and 2 patients died on the operating table before ligation could be accomplished. There was no recurrence of pulmonary embolism in the patients operated on. The authors recommend ligation of the inferior vena cava as the treatment of choice in patients with thromboembolism.

Total Gastrectomy.—Smith reviews observations in 89 total gastrectomies performed at the Lahey Clinic since 1927. All patients gave x-ray evidence of a lesion involving the stomach. The postoperative mortality for the entire group was 29.1 per cent. The postoperative mortality during the last three years and nine months of the study, during which 43 operations were done, was 16.3 per cent. Twelve patients have survived the operation for three years or more. Calculation of life expectancy of patients surviving the operation shows that 50 per cent will survive twelve months or more. It is impossible to overemphasize the importance of nutritional care in the postoperative period of patients subjected to total gastrectomy. In order to put the gastrointestinal tract as completely at rest as possible and so avoid stress at the suture lines, nothing is given by mouth for at least three days. During this period blood is transfused as indicated. With the advent of protein hydrolysates for parenteral administration there has become available a valuable addition to the postoperative nutritional care of patients undergoing gastrointestinal surgery. The author advocates the administration of one of the available digests in amounts equivalent to at least 50 to 100 Gm. of protein daily until the patient is able to take adequate protein orally.

Hyperfunctioning Single Adenoma of Thyroid.—Cope and his associates say that during the past ten years 10 patients have been cared for in the Thyroid Clinic at the Massachusetts General Hospital whose thyroid glands fulfil the anatomic and biologic criteria of a hyperfunctioning single adenoma of the thyroid. Proof of the existence of a single adenoma depends on the absence of other diseased thyroid tissue, the presence of gross anatomic atrophy and of physiologic inactivity of the uninvolved thyroid tissue, and relief of the excessive function on its removal. The atrophy of the uninvolved thyroid tissue can be suspected on physical examination but should always be recognized at operation and undue resection of it avoided. The physiologic activity of the adenoma and uninvolved thyroid gland has been compared by the ability of explanted thyroid tissue to inactivate thyroid stimulating hormone and by the avidity of the thyroid for tracer doses of radioactive iodine. The absorption of tracer doses of radioactive iodine by single adenomas not associated with hyperthyroidism suggests that the secretory activity of adenomatous tissue varies and that the presence of thyrotoxicosis in a patient depends on the degree of activity and size of the adenoma. The activity of the accompanying uninvolved tissue varies inversely and is depressed when that of the adenomatous approaches an excessive amount.

Massive Iliac Bone Grafts and Combined Bone Graft-Metallic Plate Technic.—Experience with 85 patients on whom 91 bone graft operations were performed has indicated to Horwitz and Lambert the need for variations in technic. They discuss experiences with iliac bone as massive bone grafts; conditions in which cortical bone is preferable to iliac bone as graft material; the place for plate fixation in combination with bone grafts; fixation by multiple screws in oblique fractures; modifications and variations in the technic of the combined graft-plate method and of bone grafting without plate fixation; factors involved in failure of the graft operation incidence and factors involved in the occurrence of postoperative infection, and the fate of iliac grafts in the presence of infection. Resorption of iliac grafts has occurred as late as four or five months postoperatively, owing possibly to incomplete metaplasia and structural weakness of the graft and the result of stress and strain on an inadequately protected graft. This also occurs with cortical grafts and is one of the dominant reasons for the use of internal metallic fixation in conjunction with grafting procedures. Cortical bone must be employed, for example, when grafts must be excessively long and when an absolutely straight, rigid segment of bone is required. To assure absolutely rigid protection during graft incorporation, especially when large defects are being bridged, it is recommended that the plate-graft technic be employed. Failure of bone graft operations with recurrence of *nonunion*, excluding cases associated with postoperative infections, has been due to such errors in technic as failure to use a plate when indicated and failure to use a plate of adequate length. *Postoperative infection* does not mean failure of iliac graft incorporation, especially if the infection is mild and well controlled and removal of the metallic fixation can be deferred.

Costoclavicular Syndrome.—Telford and Mottershead base their conclusions on findings at 120 operations undertaken for the relief of pressure on the neurovascular bundle of the arm; on examination of the effects of posture of the shoulder girdle on the radial pulse in 120 medical students, and on the evidence obtained by dissection of 30 bodies. No one mechanical cause can explain all cases. Damage by pressure of the clavicle cannot happen in pure depression of the shoulder but is a likely event in retraction and abduction if cervical rib or abnormal first rib is present. These cases will probably show whole plexus symptoms. The most common cause of symptoms is the hanging up of the plexus on a cervical rib or other mechanical obstacle. These cases are likely to show lowest trunk symptoms. The phenomenon of alteration in the radial pulse on movements of the shoulder is due to causes distal to the clavicle. It has nothing to do with the costoclavicular syndrome.

Endocrine Allergy.—Zondek and Bromberg suggest for the treatment of endocrine allergy (1) desensitization by the subcutaneous injection of the hormonal allergen in gradually increasing doses, (2) desensitization by the "depot method" involving the implantation of hormone pellets, (3) desensitization by percutaneous treatment with hormone ointment and (4) elimination of the allergenic hormone from the body by the inhibition of the gonadotropic hypophysial function with large doses of estrogens or androgens. In 47 cases of endocrine allergy treated by specific desensitization complete recovery was obtained in 51 per cent, improvement in 28 per cent and negative results in 21 per cent. In 2 cases the allergenic hormone was eliminated by the inhibitory effect of high doses of testosterone on pituitary secretion.

Diagnosis and Therapy of Peripheral Nerve Lesions. A. Rottmann.—p. 99.

Abdominal Amnion Puncture as Differential Diagnostic Aid.—The diagnostic amnion puncture, as used by Hoff, is based on the reasoning that in the presence of a total hydatidiform mole the entire uterus is filled with hydropically swollen chorionic villi and no amniotic fluid can be obtained by puncture of the uterine cavity. If amniotic fluid is aspirated, the unusually rapid enlargement of the uterus is not due to a vesicular mole. The author stresses that early diagnosis of cystic mole is difficult without the described method, because neither roentgenograms nor hormonal analyses are reliable before the typical vesicles are discharged. Since it is particularly difficult to differentiate a cystic mole from a hydramnion or a twin pregnancy the abdominal amnion puncture is advisable in doubtful cases. With proper regard for contraindications, the method is comparatively simple, reliable and safe.

Tumors in Pineal Body.—Müller and Wohlfart say that in the 47 cases of tumor of the pineal gland, in 28 men and 19 women, treated in the neurosurgical division of the Serafimer Hospital from 1929 to 1944, general symptoms of increased intracranial pressure appeared as a rule before local symptoms, while eye signs were absent in only 6 instances. Bilateral iridoplegia occurred in 37, reflex iridoplegia in 21, paralysis of vertical conjugated movements in 19, partial paralysis of the oculomotor nerve in 10, paralysis of convergence in 7, isolated paralysis of the trochlear nerve in 3 and paralysis of the abducens in 11. There were 13 cases of vertical nystagmus, 5 of horizontal-rotatory nystagmus and 2 of converging nystagmus. Puberty precox was not seen. Tinnitus, which may appear before the general symptoms of pressure, is an important if not especially common symptom not sufficiently noted in the literature. It has not been established that puberty precox is due to destruction of the pineal gland. The diagnosis of pinealoma or pineoblastoma was made or suspected in 29 cases; 1 case of neuroblastoma and 4 cases of intracranial teratoma were found. In the 41 patients operated on the primary mortality was 20, 11 patients died within four years after operation, the fate of 1 being unknown, 9 patients are living, 1 two and a half years after operation, 8 from six to twelve years after operation, and the 7 are able to work and are practically without symptoms.

Book Notices

The Human Frontier: A New Pathway for Science Toward a Better Understanding of Ourselves. By Roger J. Williams. Cloth. Price, $3. Pp. 314. Harcourt, Brace and Company, 383 Madison Ave., New York 17, 1946.

Williams is known to medicine primarily for his discovery of pantothenic acid and for his general contribution to our knowledge of the B vitamins. In this book he presents in language addressed definitely to the lay reader a philosophical consideration of some of the advances made by medical science. He has been especially concerned with the great variations in human physiology, a subject of the greatest importance since a determination of what is normal may be the first step in the proper consideration of the abnormal. The chapter on the endocrine glands and behavior reviews our knowledge of the glands and the manner in which they regulate our lives. He concludes from his study that standards of what may be regarded as a normal sex life do not exist and lead to the concept that it is futile to expect that each human being will behave according to a pattern that we ascribe to the average man. Following the discussion of physiology there is an extensive consideration of psychologic traits and the conclusion that every consideration leads us to think that psychologic phenomena have physiologic bases. There is a fundamental unity between one's physiology and one's psychology, a relationship that leads logically to a greater appreciation of psychosomatic medicine. The author proceeds to a consideration of man and society, to humanics and education, to a review of marriage clinics, then to clinical and to medical research. A final chapter deals with international relations. The book represents therefore essentially a series of essays on life based on scientific knowledge. He concludes that the scientific method is not applicable to the furtherance of art, music, literature or religion, but science can demonstrate its efficacy in modifying human essentials and can appraise the progress of man toward established spiritual goals.

Demonstrations of Physical Signs in Clinical Surgery. By Hamilton Bailey, F.R.C.S., F.I.C.S., Surgeon, Royal Northern Hospital, London. Tenth edition. Cloth. Price, $7. Pp. 375, with 573 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

This gem of descriptive clinical surgery can boast without doubt that it is a familiar property to every medical student who reads English. While the text is clear and concise, its greatest value lies in the profuse and wonderful illustrations which it contains. The book is a bulwark of physical diagnosis and pointedly demonstrates how often the surgeon can arrive at a working diagnosis with the use of his five senses. Experience will create a sixth. There is little need of describing the content in detail; except for revisions of minor character and improvement and additions to the pictorial data, this edition is quite similar to previous editions. While the book is of the same size, there are many more illustrations than in former years. It is a delight to recommend the volume to every clinical clerk and intern.

Pointers for Parents. By Reinhard V. Lozier, M.D. Cloth. Price, $2. Pp. 141, with illustrations. J. B. Lippincott Co., 227 S. Sixth St., Philadelphia 5, 1947.

As suggested by the title, this book consists of instructions to parents. While, in general, the attitude of the author is kindly and friendly toward parents and children, it seems entirely too much weighted on the side of inflexible instruction and affords too little of the information concerning the basis of this instruction. "Do's" and "don'ts" entirely dominate "whys" and "wherefores." The differences in human personality are so complex that it is confusing to attempt to make such hard and fast rules when dealing with children and their parents. It is confusing to a mother to be told that nothing should ever interfere with her daily program with the baby. Such regimentation is impossible and probably not desirable in any family. The author advocates a training routine which is entirely too advanced in comparison with the schedule now accepted by most students in the field. This again is confusing to children and mothers. One finds oneself confused when the author mentions research which implies that breast milk may carry the hereditary tendency to cancer to children. While this point of view has been held by some students of genetics, it is not an accepted fact and therefore should not be broadcast to laymen without considerable caution. This book adds nothing constructive to the already voluminous literature on child care. The author does not seem to have the tentative attitude so important in discussion of human relationships. The many lists of hard and fast rules will tend to lend confusion rather than clarity to solution of the problems of parents.

Traitement chirurgical du cancer du rectum. *Par François d'Allaines,* professeur agrégé à la Faculté de médecine, Paris. Avec la collaboration de A. Le Roy et Ch. Dubost. Paper. Price, 1,100 francs. Pp. 218, with 67 illustrations. Éditions médicales Flammarion, 22, rue de Vaugirard, Paris, 6e, 1946.

In this volume the author and his co-workers discuss the results of treatment of 263 patients suffering from carcinoma of the rectum. The study covers a period of ten years. The first chapter deals with anatomic considerations and is devoted chiefly to information gained from the writings of leading authorities on the subject of lymphatics. In chapter two the authors discuss diagnosis and various factors which they believe important in determining the operability of malignant lesions. A clear statement is provided regarding operability when preservation of the sphincters is desirable. The advantages and disadvantages of the various operative procedures especially of those employed to preserve the sphincteric mechanism of the anus and of palliative procedures are explained. In chapter three the technics of operative procedures are presented. In the authors' series 92 per cent of the patients were considered to have operable lesions, and a radical operation was performed in 233 cases (85 per cent). These authors prefer a one stage combined resection. In chapter four the importance of creating a temporary colonic stoma at the time of the operation is stressed. This stoma should be made in the left portion of the colon, but if this portion is not available it can be made in the transverse colon. In chapter five a comprehensive discussion is provided regarding preoperative and postoperative care. In chapter six the method of abdominosacral resection with the preservation of the anal sphincters employed by the authors is described. More than thirty fine illustrations are provided to clarify their presentation. In chapter seven more fine illustrations with legends show the Kraske procedure, Babcock's method of preserving the sphincter and the variations of technic which are made necessary owing to a short colon, sex of the patient and so forth. In chapter eight the technic of combined abdominoperineal resection is illustrated and described in the legends. In chapter nine complications such as fistulas, abscess formation, herniation and stenosis are described. In chapter ten the authors compare their results with those of other authors, and a final plea for early diagnosis concludes this splendid work.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Cumulative Supplement 1946. Medical Progress 1946. Editor in Chief: *Rt. Hon.* Lord Horder, G.C.V.O., M.D., B.Sc., Physician to the King. Boards. Cloth. Price, $12. Pp. 267; 498. Butterworth & Co., Ltd., 1367 Danforth Ave., Toronto 6; 4-5 Bell Yard, Temple Bar, London, W. C. 2, 1946.

This summary of medical progress in 1945 begins with a brief statement by Lord Horder on social medicine. The book then takes up the various medical specialties seriatim and by references to available periodical literature indicates the innumerable brief steps in medical progress that occur in any given year. Essentially the work may be considered a collection of abstracts with an occasional brief critical review.

Food Values of Portions Commonly Used. Compiled by Anna de Planter Bowes, M.A., and Charles F. Church, M.D., M.S. Sixth edition. Paper. Price, $1.60. Pp. 58, with 1 illustration. Anna dePlanter Bowes, 311 S. Juniper St., Philadelphia 7, 1946.

This compendium has passed through many editions and has come to be recognized as one of the most valuable guides available on the values of foods as commonly served. The authors avail themselves of tabulations made by the government and other agencies, so that the figures presented are quite up to date.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RECURRENT MALARIA

To the Editor:—A man aged 40 had an acute attack of vivax malaria (discovered on a blood smear) following lobar pneumonia in January 1946. He had had malaria at the age of 15 without subsequent episodes and two attacks of sinusitis. He was not in military service. For the present attack he was given large doses of quinine, followed by atabrine 28 grains (2 Gm.) for one week and then 3 grains (0.2 Gm.) daily for three months. He has not felt well since January. In December 1946 he had symptoms of aching, chilliness and weakness. The smear was again positive for vivax malaria. The patient was given atabrine 12 grains (0.75 Gm.) a day. In four days he developed generalized severe pruritus, urinary frequency and burning, with frequent chilliness and leg aching. General physical examination is negative. Blood chemistry studies, blood counts and urine examination are negative. What treatment is suggested? Are any new drugs available?

M.D., Connecticut.

ANSWER.—Malarial recurrence after twenty-five years is not too infrequent, although most cases of this description are quartan malaria rather than vivax. It is unusual for vivax malaria to become reactivated after this length of time, even subsequent to shock or surgical operation. The refractoriness exhibited toward quinine and atabrine (quinacrine hydrochloride) could mean an infection acquired from a veteran from the Pacific. The large doses of both quinine and atabrine should have been adequate even if it was of this variety. Other kinds of infection should be excluded.

One of the new noncurative drugs, chloroquine, is now available, marketed as the diphosphate salt, under the name Aralen Diphosphate (Winthrop Chemical Company). The dosage is six tablets (0.25 Gm. each) the first day, then two tablets (0.25 Gm.) each of the two following days. Total dosage 2.5 Gm.

CORNEAL TRANSPLANT

To the Editor:—A patient is totally blind because of scar tissue from injury by a strong lye solution. The retina in this case is probably normal but he has been told that a transplanted cornea would soon become vascularized and therefore would not be successful. Is experimental work being done on global transplants? Who is doing this work?

M.D., Washington.

ANSWER.—Work is being done at the Wilmer Institute, Johns Hopkins University, Baltimore, and at the Eye Institute, Presbyterian Hospital Unit, Columbia University, New York, and at the Eye Bank for Sight Restoration, New York, on the use of x-rays in the treatment of vascularized scars of the cornea as preparation for a possible future corneal transplant. The transplantation of the entire eye is impossible because it is but an outgrowth of the brain, and the severance of the optic nerve produces irrevocable blindness. It is impossible to graft all the small blood vessels that are necessary for the nourishment of the interior of the eye.

VITAMIN A AND DARK ADAPTATION

To the Editor:—What is the current medical opinion concerning the efficacy of a daily dose of 50,000 units of vitamin A for promoting dark adaptation of eyes for fluoroscopy? Is a greater or lesser dosage necessary for the latter? What possible disadvantages are there to the taking of such large doses daily?

M.D., California.

ANSWER.—The consensus based on many reports is that the administration of vitamin A does not have any effect on the dark adaptation of persons who are not already deficient in this vitamin. Although many radiologists feel that daily ingestion of vitamin A improves their vision in fluoroscopy, there has been no experimental evidence advanced to substantiate this belief. In fact, unpublished reports have indicated that there is no improvement. However, if dark adaptation is subnormal the ingestion of vitamin A may increase the vision in fluoroscopy (Lerner, H. H.: *Am. J. Roentgenol.* **45**:753 [May] 1941).

The daily allowance of 5,000 international units of vitamin A for the healthy person was recommended by the National Research Council in 1945. If the radiologist has no vitamin A deficiency the daily doses of 50,000 units is excessive, although it is harmless.

HEXAETHYL TETRAPHOSPHATE

To the Editor:—Would you kindly advise me what toxic effects hexa-ethyl-tetra-phosphate (known as bladan in the German literature) has on man. I understand this substance is used as an insecticide.

M.D., California.

ANSWER.—This insecticide is manufactured by the Monsanto Chemical Company in St. Louis. After use on fruit trees the substance rapidly becomes innocuous because of hydrolysis in the presence of diluting water. For this reason it becomes unnecessary to wash fruits or vegetables prior to consumption —at least unnecessary so far as possible damage from this insecticide is concerned. So rapid is its disintegration that approximately four hours after admixing with water it loses its identity. Hexaethyl tetraphosphate ($C_{12}H_{30}O_{13}P_4$) is an amber liquid capable of corroding some metals and damaging some minerals such as some porcelains. Properly applied, it is not damaging to most vegetation but is destructive of most the forms of insect life unharmed by DDT. For animals it is highly toxic, but experience so far has not included man. It is presumed to be injurious to man. When applied to the skin of rats 0.2 cc. per kilogram of weight is fatal, and when administered orally to rats 0.005 cc. per kilogram is fatal. These animal results indicate that skin contact and inhalation by human beings should be avoided. Contaminated skin areas should be washed in water thoroughly and immediately. Respirators should be worn whenever there is the likelihood of inhalation or ingestion. Any exposed persons who develop headache or a sense of chest constriction should be removed promptly from further exposure until fully recovered. This information was obtained from the manufacturer, who has been unusually cooperative and is fully desirous that this substance be applied with due consideration for requisite safeguards.

HEMORRHAGIC STATE IN LEUKEMIA

To the Editor:—Please answer a question that has bothered me for a long time: "What is the mechanism of hemorrhagic disease in uremia?"

Merrill C. Beecher, M.D., Knoxville, Ill.

ANSWER.—There are several possibilities for a hemorrhagic state in uremia: necrosis of small arteries and arterioles in the nasal and gastrointestinal mucosa in persons with severe hypertension; increased capillary permeability on a toxic basis; low platelet count due to severe depression of bone marrow function; low prothrombin level in the blood due to dietary deficiency, impaired absorption of vitamin K or impaired liver function; vitamin C deficiency. The last three factors operate only rarely in the average case of uremia. Presumably the most likely reasons for uremic hemorrhages are toxic damage to capillaries, hypertensive arteriolar necrosis and gastrointestinal ulceration. The addition of congestive heart failure would aggravate the tendency to bleeding.

PREGNANCY AND MULTIPLE SCLEROSIS

To the Editor:—A primipara aged 23, who is eight months pregnant, is afflicted with multiple sclerosis. She can hardly walk at the present time. Abdominal reflexes are absent. What are the prospects for a normal delivery in such a case? Is a cesarean section indicated?

P. G. Berkhout, M.D., Paterson, N. J.

ANSWER.—Many patients with multiple sclerosis have had normal deliveries. When the patient has paraplegia and is unable to walk there is always the possibility that she might have difficulty in spontaneous delivery. Because the puerperium can precipitate or aggravate an attack of multiple sclerosis, cesarean section and sterilization are recommended.

DERMATITIS FROM COMMERCIAL ULTRAVIOLET LAMPS

To the Editor:—Have cases of dermatitis from "Pasturay" lighting fixtures been reported? This type of lighting is used in meat handling in some factories and purportedly emanates ultraviolet light for antiseptic purposes.

M.D., Ohio.

ANSWER.—It is possible to contract actinic dermatitis and conjunctivitis from excessive exposure to ultraviolet light used for antiseptic purposes. However, records of such cases are not common.

HARMFUL OCULAR EFFECTS OF PHOTOFLASH LAMPS

To the Editor:—Will any harmful effects on an infant's eyes result from the use of photoflash lamps when taking photographs? The child is 2 months old and the photoflash lamps are General Electric No. 5.

Ralph Burbridge Jr., M.D., Allentown, Pa.

ANSWER.—There are no known harmful effects.

THE MOVING FINGER WRITES

Address at Centennial Dinner, American Medical Association,
Atlantic City, N. J., June 7, 1947

H. W. PRENTIS Jr.
President, Armstrong Cork Company; Past President, National Association of Manufacturers
Lancaster, Pa.

The law of compensation is inexorable. For threescore years I have been operated on physically, admonished mentally and laid upon orally by a countless succession of members of the American Medical Association. Now my hour has come. And you can rest assured that it is no small pleasure to me to have such a goodly company of you gentlemen at my verbal mercy—even though the expiation you are called on to render is necessarily vicarious in character.

A hundred years is but a split second in the chronology of the cosmos. It is a long time, however, in the calendar of mortal men. It is even more significant when applied to the life span of a voluntary organization of highly individualized professional experts scattered over a huge geographic area. Hence I consider it a signal honor to have been asked to join with you tonight in this, your Centennial Celebration.

In 1855 Dr. N. S. Davis predicted that, "of all the voluntary social organizations in our country, none are at this time in a position to exert a wider or more prominent influence over the temporal interests of our country than the American Medical Association." The decades that have since elapsed bear abundant testimony to the truth of his prophetic assertion. No grass has ever grown under the Association's feet. At its very first session in 1847 it began a fight for higher educational standards for the medical profession, urged the separation of "the business of teaching" from the "power of licensing," advocated uniform state laws for the registration of births, marriages and deaths and set about the preparation of a "General Nomenclature of Diseases" and a Code of Medical Ethics. In the year immediately following there came a resolution declaring that "every system of medical instruction should rest on the basis of practical demonstration and clinical teaching" and a memorial to Congress requesting the inspection of imported drugs to prevent adulteration—the forerunner, I take it, of our modern Food and Drug acts.

At the third annual meeting in Cincinnati in 1850 a discussion of medical literature led to the adoption of a petition to the federal government for an international copyright law along with what your old historian calls "an eloquent and truthful paragraph in relation to the nature and influence of a national literature of our own." With all of the subversive propaganda to which we are now subjected, that paragraph is well worth quoting: "Our institutions are peculiar and, in order to be legitimately carried out, should not only be well understood by all concerned but should be supported by habits of thinking and feeling in the community in full accordance with them." Had that sage advice been followed, our republic would not be facing many of the domestic problems with which it is confronted today.

The following year—1851—the fourth annual meeting was held in Charleston, S. C. Most of the Northern contingent journeyed down by sea. There was a heavy gale and it is duly recorded that "the rocking of the ship soon awakened a large proportion of our doctors, with feelings very much as though they had swallowed half of the ipecac in a respectable drug shop." Specific note is also made of the fact that in Charleston "for the first time in the history of the Association, wines and strong drink were freely furnished as a part of the entertainment!"

It has in truth been a remarkable hundred years—a century of well directed, collective effort of which the Association may indeed be properly and pardonably proud. Always in the forefront in the fight for higher standards of medical education and professional ethics, its far-flung technical services have set a mark for scope and efficiency unequaled in any similar organization elsewhere in the world. So both as an American citizen and as a grateful beneficiary of its myriad accomplishments in the field of private medicine and public health I congratulate and salute you—its members—confident that the second century of the Association's service will be even more fruitful than the one that has now come to such a praiseworthy conclusion.

Since we are honored tonight with the presence of the greatest military Omar in history—General Omar Bradley—it seemed not inappropriate to select for my subject "The Moving Finger Writes," a phrase from the poem of his namesake—"in reverse lend lease"—Omar Khayyam:

> The moving finger writes and, having writ,
> Moves on; nor all your piety nor wit
> Shall lure it back to cancel half a line,
> Nor all your tears wash out a word of it.

The moving finger of history is never still. Day by day it records relentlessly our national achievements and our popular follies; our vagaries of mass insanity and our decisions of collective wisdom. For good or ill, the revolutionary changes in our approach to the problems of government during the past fifteen years stand stark and irrevocable, filled with the promise of freedom or the latent menace of tyranny, as only the future will reveal.

Some of these changes, I fear, would seem strange and sinister indeed to the men who laid the foundations of this republic. For, as their writings clearly indicate, theirs was no makeshift experiment. It was based on an exhaustive study of all previous attempts at popular self government in the world's history; on a determined effort to discover the hormones of a free society—the basic principles on which men may associate themselves to enjoy permanently the priceless blessings of liberty.

THE HORMONE OF COURAGE

The word hormone, as you well know, comes directly from the Greek and means literally to set in motion. The founding fathers, in brief, sought in our peculiar system of government to set in motion those fundamental forces and safeguards and incentives that are essential for the maintenance of human freedom. So we may well ask ourselves in these days of confusion What are those social hormones? To what extent has their action been crippled by individual ignorance and apathy; constricted by misguided humanitarianism and lust for political power, circumvented by the impact of modern industrial civilization and the rising tide of world collectivism?

The hormones of a free society are not many in number, but all are vitally essential to the effective functioning of a free body politic: self reliance, local responsibility for local affairs, personal initiative, thrift that leads to individual economic competence, social cohesiveness—the absence of class consciousness, tolerance, patience, civic virtue—the willingness to work and sacrifice for the public interest, belief in the dignity of the individual, courage. You may think of other social hormones, but these at least must be kept flowing freely in the blood stream of our people if our republic is to survive. The thyroid extract of initiative, the pituitary secretion of civic virtue, the adrenal hormone of courage and all the others are of transcendent importance to any nation of free men that seeks to preserve its liberty.

THE THREAT OF STATE SOCIALISM

In recent years the moving finger of history has recorded quite a disturbing story in respect to these basic characteristics on which our free institutions rest. I cannot attempt to discuss all of them so, as a typical example, let me take self reliance. The idea is not popular these days. Too many of us are prone to try to shoulder our troubles off on government—men and women no better, no worse on the average than the rest of us. When we do that and cease to rely on ourselves, look what happens:

Government paternalism decreases local responsibility for local affairs and increases the size and cost of the central government. This inevitably leads to higher taxes, reduced personal incomes and less opportunity for the individual citizen to become financially competent. As a result, the amount of venture capital available for new enterprises is cut down, and more and more government intervention is demanded to maintain employment. This process still further increases the cost of government and thus, working in a vicious circle, eventually creates a state of national neurasthenia that deranges the entire social endocrine system. The ultimate outcome is the destruction of democracy and the emergence of some form of authoritarian government. The old Greek historian Polybius was right in observing two thousand years ago that, when there has been "created among the masses an appetite for gifts and the habit of receiving them, democracy in its turn is abolished and changes into a rule of force."

Now no one is more willing than I am to admit that the modern industrial age with all the benefits it has brought to the average man has also created a host of problems for him. In most cases the individual worker no longer owns his tools of production. He can no longer turn readily from factory to farm or from farm to factory as economic conditions change. Frequently he is powerless to find immediate means of support when technologic advances throw him out of work. But as I see it the mistake that we have made is that in seeking ways and means to compensate for such conditions we have slavishly copied procedures that were not developed for our kind of government.

When a transfusion is indicated, the type of the patient's blood must first be ascertained. So it is with the body politic. Whenever governmental intervention is deemed necessary, it should be thoroughly consonant with the activating principles—the social hormones—of our free society. As your Association pointed out in 1850, "our institutions are peculiar." Hence a social security program devised to placate the German people in the 1880's was not necessarily the type best adapted to the United States. Yet, when we did go in for old age pensions on a national scale ten years ago we adopted well-nigh lock, stock and barrel the centralized procedures originally recommended by Bismarck two generations ago. As a result we have a huge bureaucracy on our hands known as the Social Security Administration that costs us tens of millions of dollars a year. Would it not have been far wiser to install a system especially adapted to our own American traditions? Let me be specific: Approximately 3,750,000 workers in the United States were covered by private pension plans in 1929—long before the federal Social Security Act was passed. Suppose our government had set about to expand the development of such voluntary efforts. Several approved programs could have been set up for administration through private insurance companies. The employer could have been encouraged to adopt one or the other of such plans through appropriate tax credits and the right to use some official insigne indicating that the employer had a governmentally approved pension program. Under such procedure no unwieldy bureaucracy would have been required and a goodly portion of the reserves set aside to finance pensions would have been siphoned back at once into the blood stream of industry and commerce, creating more jobs and more production. As it is, the enormous funds that have been accrued are virtually sterile so far as the creation of new taxable wealth is concerned, since they are either being spent currently for the running expenses of government or invested in non-income producing public works. They actually do not exist except as entries on the government's books. Desirable as the objectives of our social security program are, the means employed have certainly not been those that are best adapted to the genius of our free institutions.

Now the moving finger of history is writing again: A similar centralized system of health and hospital insurance is being urged upon us. Do we intend to repeat the same process and strangle still further the principles of self reliance and local responsibility for local affairs, which are two of the root principles on which our freedom rests? I hope not. And therefore as a citizen I have rejoiced in the growth of the Blue Cross and other voluntary plans for hospital and health insurance which have been formulated and encouraged by this Association and its affiliated bodies.

Of course, the development of such voluntary programs will not satisfy those well intentioned but short sighted humanitarians who demand sweeping and immediate action regardless of the ultimate effect on our national character and way of life. The besetting sin of reformers has always been lack of patience—failure to recognize that, as Dr. Davis observed in 1855, "the whole history of the human race shows that all great and true reforms, whether social, moral or political, proceed slowly." One of the obvious virtues of voluntary plans for hospital and health insurance is that such programs do not require the setting up of ponderous public agencies to run them.

Four hundred years before Christ, Plato said "Democracy contains no long-range force which will check the constant tendency to put more and more on the public payroll." Certainly the truth of this assertion is thoroughly exemplified by the happenings of the past fifteen years. There were some 630,000 civilian employees in the federal government in 1933. The number rose to a peak of approximately 3,826,000 during the war and today stands—nearly two years after the close of hostilities—at approximately 2,247,000. The average cost of each civilian employee is approximately $2,650 per annum. So this huge governmental establishment is one of the factors that have raised federal expenditures to their present fantastic levels.

During the ten seconds that I have held this burning match in my hand the federal government has spent approximately $12,000. Spending is going on at this moment at the rate of $4,200,000 per hour; over $100,000,000 per day; about 40 billions per year. Incidentally, I wonder how many Americans have the faintest conception of what a billion is. If you had employed a thousand men at $5 a day in the year 1398, ninety-four years before Columbus discovered America, and worked them every day, year in and year out, you would have used up your first billion dollars in 1946!

During the war it was necessary, of course, to spend without stint or limit to gain a speedy victory. We find ourselves now, however, confronted with a proposed budget for the fiscal year which starts on July 1 of 37½ billions—equivalent to 37 eight story buildings where each inch of height is a million dollars! State and local expenditures will add up no doubt to another 15 billions. With a total national income estimated at $170,000,000,000, this means that more than one dollar out of every four dollars of value produced will be taken by the tax gatherer during the next twelve months.

Now political freedom cannot long endure in a republic in the absence of a financially competent citizenry. If even a substantial minority of our people became wards of the state, our two party system would evaporate and with it our liberty. Hence the present enormous tax burden creates a fiscal carcinoma that gnaws away at the very vitals of our free society. The American people generally do not realize what has been done to them in the past ten years. The social hormone of thrift that leads to economic independence is already seriously affected by a process of financial metastasis. With income and estate taxes and interest rates at their present levels it is now virtually impossible for a young man starting at scratch, in either a profession or in business, to accumulate a competency for his own later years and his family after he is gone. Thus the faith and courage of our people are being insidiously weakened as the prospect of a self-respecting and independent old age fades and disappears. The present personal income taxes, corporate taxes, capital gains taxes and the ever present threat of taxes on accumulated surplus make the development of small businesses in the future a well-nigh insurmountable task and seriously handicap the growth of many existing enterprises. Yet the expansion of existing businesses through the plowing back of earnings and the constant injection of new enterprises into the economic blood stream of our national economy are absolutely essential to the continued operation of our private, competitive business system. If funds for such purposes cannot be had from private sources and government supplies them, state socialism automatically results.

Consider too the plight of the one third of our population who allegedly are ill nourished, ill housed and ill clad. In the last analysis who but the financially competent among us can help that situation? Of course, government can tax away the savings of the competent of this and past generations and distribute them, but eventually when this accumulated fat is gone where is new productive wealth to come from in a free society if not from the ingenuity, initiative and thrift of the competent? It is therefore high time, it seems to me, for all believers in American liberty to raise their voices in behalf of the two thirds of our citizens who have proved able to take care of themselves and thus show some concern for the original "forgotten man" of William Graham Sumner—the quiet citizen who paddles his own canoe day in and day out, marries and raises a family, meets his bills promptly, pays his taxes, supports his church, contributes to the community chest, fights for his country when need arises, asks nobody to protect him from "cradle to the grave" and thereby does his quiet bit to maintain the American republic for his children and his children's children!

The moving finger writes. Little or no consideration has been given thus far to the ultimate effect of "cradle to the grave" paternalism on our standard of living.

When virtually all responsibility for the ordinary hazards of life are removed from the individual's shoulders, when the Biblical injunction "in the sweat of thy face shalt thou eat bread" is nullified, when a job hangs not on every limb but on every twig, what motive is left that is sufficiently impelling to insure the full production on which our high living standard depends? Personal pride, of course, may drive some men on, despite the fact that under present surtaxes the individual may find himself—figuratively speaking—netting one dollar for his first hour's work, seventy-five cents for the second hour, fifty cents for the third hour and fifteen cents for the fourth hour! But those for whom pride of accomplishment is a sufficient reason for giving the best that is in them are a microscopic minority of our whole population. In the absence of a certain modicum of fear as to what may happen if a man does not produce all he can, what is going to keep production at high levels in the face of full employment?

Sir William Beveridge, the great apostle of government planning to insure full employment, has never been able to answer that question. He fails to come to grips with it in his books and indulged in a lot of wishful thinking about it when pressed for an answer over the luncheon table. When the old proved hormones of self reliance, personal initiative, thrift and the willingness to work are neutralized by the virus of government paternalism, a sort of spastic paralysis ensues in the body politic. The wellsprings from which our high living standards flow are choked. The fountains of political freedom dry up.

Men apparently cease to exert themselves in about the same proportion that the state assumes their support. Then the Russian solution of the problem of full production, namely depriving the drones and laggards of food cards and living quarters, logically follows. Significantly enough, I noted a few weeks ago that one of the left-wing leaders in England was reproaching the Labor Government for not having adopted the Soviet procedure. Fantastic as such a recommendation sounds coming from British lips, it must be weighed in the light of other revolutionary happenings in a country that until recently was a mighty fortress of personal freedom.

You will be as shocked as I was the other day when I learned that no less than seventeen ministries in Great Britain now possess the power to enter private homes without search warrants in enforcing the rules and regulations dealing with the nation's planned economy. The Englishman's house is no longer his castle. Nevertheless, Herbert Morrison, Lord President of the Council, said on May 1 "It is not that we have governed too much, but that in some ways we have not governed enough." Yet here in the United States we have certain vocal advocates of the so-called "middle way"—that mythical type of government that could allegedly take over the planning of our economic affairs and still preserve our political, intellectual and spiritual freedom.

As I understand it, when the secretion of the adrenal glands is interfered with, Addison's disease ensues. The patient, among other symptoms, becomes terribly nauseated and, unless the endocrine deficiency can be soon compensated for, the malady is inevitably fatal. So it is with class consciousness in a representative democracy. When the hormone of social cohesiveness disappears in the body politic, history shows that the decline and fall of popular self government is sure to follow. In recent years class feeling has raised its ugly head in America. We have seen the rapid emergence of labor groups, farm groups, youth groups, veterans' groups—some of which class divisions have, sad to relate, been intentionally accentuated for partisan political purposes. The nation has been subjected to repeated attacks of violent economic nausea which now bid fair to result in political lesions of a horizontal nature instead of the vertical cleavages that have characterized our political contests in the past. The moving finger writes. In the face of the portentous record it has made of rising class consciousness in recent years, the patriotic citizen will spare no effort to restore that basic spirit of national unity on which the preservation of democratic government depends. It is later than we think.

THE DUTIES OF CITIZENSHIP

Francis Quarles—the old English poet—made this sardonic observation in the year 1638: "Physicians, of all men, are most happy. Whatever good success soever they have, the world proclaimeth; but what faults they commit, the earth covereth." Certainly there is one fault of doctors—and plenty of the rest of us too—that the future will not conceal, namely our apathy in respect to the duties of citizenship. The events of the past fifteen years have proved definitely that mere professional or managerial proficiency is not enough to preserve the environment of freedom. Too high a degree of self-centered specialization in the learned professions or in industrial management is self defeating in the field of politics and public relations. Many of us have become so absorbed in handling our personal jobs efficiently that we have forgotten that the game itself cannot continue very long if the fields—local and national—on which it must be played are not kept in good order. In other words, as you doctors have concentrated on being highly skilled professional experts and we men in industry on trying to be able managers, we have far too often become poor citizens and left the affairs of the major league—the national economy—to politicians and reformers. If our type of free society is to be preserved, professional and business men must not only be good technicians but also good citizens in every sense that those words imply. Civic virtue—the willingness to work and sacrifice for the public interest—is an indispensable hormone of freedom. A deepened and broader concern with public affairs on the part of the medical profession generally would add further luster to its well earned reputation for unselfish service so aptly expressed in Lord Bryce's pithy comment "Medicine is the only profession that labors incessantly to destroy the reason for its own existence."

Of all the hormones that have united to create what we call the American system, the most fundamental is the value that we have given to human personality. No former people has ever conceived of individual human dignity and worth in terms which have been common to us. This concept has a distinctly religious origin which can be traced back to the fifteenth century, when John Wyclif first placed his translations of the New Testament in the hands of the common people of England. How deeply rooted this concept became in the generations that followed is evidenced by John Adams's assertion, when the Constitution was under discussion, "You have rights antecedent to all earthly government; rights that cannot be repealed or restrained by human laws; rights derived from the Great Legislator of the Universe." Today, unfortunately, far too many people define the dignity of man in terms of his physical scale of living rather than by his moral and spiritual standards.

There, it seems to me, is the basic issue in the current world crisis. If one believes that as individuals we are endowed with certain divinely given, inalienable spiritual rights, then our system of government, our free economy, our civil liberties, have a firm foundation on which to rest. If the existence of such natural rights is denied, collectivistic principles displace the individualistic principles on which personal liberty depends. And to make collectivistic principles supreme requires inevitably the submergence of the individual and the emergence of the controls of the totalitarian state. Hence, without being a pietist or the advocate of any particular type of religion, one must recognize, it seems to me, that the idea of a sovereign God endowing the individual with certain inalienable spiritual rights is fundamental to the permanent existence of the American system. Here every thinking citizen might well examine the inner recesses of his own soul and determine conscientiously how best he can contribute toward the revival in America of that supreme hormone of liberty—the concept of the sacredness of the individual in the eyes of a sovereign God.

The Greeks said "Know yourself," the Romans "Be yourself," the Christians "Give yourself." The cult of civic competence—as our fathers knew and practiced it, fused these three swords of the spirit into the great instrumentality that set them free. To remain free we, their descendants, must pay the same price they paid, for freedom is not a gift of heaven. It must be won and rewon by every generation for itself. It is not ours for the asking, as so many complacent Americans seem to think. It is ours only for the taking—through competent personal effort in support of the eternal principles on which it rests.

The moving finger writes. What it writes about this fair land of ours in the momentous months and years ahead depends not on this thing we call government but on you and me and millions like us scattered all over America. As citizens we are masters of our fate, the captains of our national soul. Shall we let our priceless heritage of freedom go by default? Shall we permit the old historical cycle to repeat itself in America: From fetters to faith, from faith to freedom, from freedom to folly, from folly to fear and from fear back to fetters once more?

The moving finger writes. We sit here tonight at this banquet board celebrating the splendid achievements of that great company who during this century past have gone before us on life's journey and left the world better because they passed through it. It is fitting so to do—to add to our meed of praise and grateful appreciation. But as we do so in humility and reverence we might well descry again that moving finger of a bygone day, as it recorded its fateful message on the wall of Belshazzar's banqueting hall twenty-five hundred years ago, firmly resolving that it shall never be written of us twentieth century Americans that we were "weighed in the balance and found wanting" in the age-old struggle for human freedom.

THE AMERICAN WAY

Address at Centennial Dinner, American Medical Association, Atlantic City, N. J., June 7, 1947

BASIL O'CONNOR, LL.D.
Chairman, American Red Cross; President, National Foundation for Infantile Paralysis, Inc.
New York

I think I speak with modesty when I say that in the last quarter of a century, because of the opportunity I have had to work in the fight against infantile paralysis, no layman in this country has had closer or more contacts with the members of the American Medical Association than I have had. That experience in itself has made life tremendously interesting.

Each year I continue to be more than before amazed by the amount of time, thought and energy that the members of this great organization give to all the health, welfare and humanitarian organizations in this country, to say nothing of the charitable service which they give all over our land to the individual directly.

How these men can travel back and forth across the country to attend medical meetings from which comes the advice so badly needed by these health and welfare organizations; how they find time to study the problems these organizations have and still pursue their professional calling are still mysteries to me.

I am glad, therefore, to be here tonight if for no other purpose than to pay my respects to this great body of men and to say that in my time I am certain that no group has made a greater contribution to the American way of life than have the members of the American Medical Association.

In the advancement of our American way of life we have gradually developed patterns of thought and action which would in many instances seem to be the inevitable development of a democratic civilization such as ours. The whole world has become more and more security minded. There was a time when an American citizen thought that the only necessity of life was a job for the father, who then assumed the responsibilities for the care of his family, including such fundamentals of living as food, clothing, housing and medical care. The one contribution which he expected from his government was a public system of education so that every child born in a free nation would be given opportunity to develop to the utmost his intellectual faculties.

Under this concept of life we developed in the United States an independent people whose progress toward attainment of a high standard of living was greater than that of any other nation in the world, and no one can appreciate that more than I can, having just returned from another three weeks in Europe and Italy. True, the natural resources of our country played a considerable part in this result, as did also no doubt its climate and the building of a special type known as the American product of a melting pot to which all the peoples of the world made their invaluable contribution.

With the turn of the century came the introduction of new technics of mass production, first in the automobile industry and then gradually extending to every other type of industrial life. There are those, of course, who think that the tendency of such methods is to submerge the artist and craftsman and to level the mass of the people. No doubt much of the interest of the worker in his job was lost when he became a unit on a production line.

In 1883 the concept of social security was introduced in Germany—a concept that was strongly recommended by the ruling agencies of most European nations and indeed by practically all nations in which a small ruling class dominated the people. It introduced a system whereby the individual looked to the state to provide him and his family with many of the essentials of life and living that American workers were accustomed to provide for themselves. The state began to be responsible for education, for housing, for medical care, for the care of the aged, for employment, for relaxation, for protection and for the care of the veteran.

Some states moved more rapidly in this direction than did others. In Germany, for instance, the state assumed more and more of these responsibilities and increasingly took a share of the workers' wages and of the employers' income to support a swollen bureaucracy that administered the system. England displayed little interest in such proposals until 1912, but today Great Britain, with the rise of a socialist and labor party, seems to be moving toward the same governmental assumption of responsibility for every aspect of the individual citizen's activities that marked prewar Germany.

Now there are many who believe that Germany moved inevitably toward the totalitarian system that enslaved her people and destroyed their morals and broke down even the ethical tradition of her medical profession as a result of the extent to which the citizens lost more and more of their personal responsibilities. The Russian civilization is comparable in many of its aspects.

Now in the United States our people thought little of social security until the great depression of 1929, when it became necessary for the government to assume complete responsibility for vast numbers simply because of the rise of unemployment and the increasing age of our population. In planning to meet these contingencies, the Congress passed a federal security act which compelled the worker and the employer to set aside funds to care for those who are unemployed for at least a certain length of time and to provide a minimum of money for the aged with which they may purchase the necessities of life. The then President of the United States, Franklin D. Roosevelt, urged the devotion by the Congress increasingly of funds to care for the indigent and to aid particularly those states which were unable with their own resources to maintain a suitable level of disease prevention and medical care.

In the evolution of this society the people of the United States, as I have said, have developed certain patterns of conduct, certain types of finance, in considerable contrast to methods that prevail elsewhere. I think it very essential that from time to time these patterns of conduct be emphasized to the American people so that they may realize more and more how their needs are met and the part which they themselves play as free citizens of a democracy in assuring to all the people of our country a quality of security above that available anywhere else in the world. I refer, of course, to the growth of our great philanthropic agencies, such as the American National Red Cross, National Tuberculosis Association, American Cancer Society, American Heart Association, National Foundation for Infantile Paralysis, National Society for Crippled Children and Adults and many other similar groups. These organizations of a peculiarly American type are maintained by funds derived from the mass of the people. The money is given to them voluntarily by people who are convinced of the good that they do. The organizations are led by individuals who join together for the common good and who in the vast majority of cases devote themselves to the advancement of these organizations without any thought of emolument in terms either of money or of prestige.

There is among these organizations a friendly rivalry not only in seeking the funds by which they live but in the maximum accomplishment that they may attain with such funds. To the services of these agencies the medical profession devotes vast amounts of time and professional talent and even its own funds. The good that these organizations accomplish needs no recapitulation to the American people.

Where else in the world can a patient suffering with a crippling disease be given all the benefits of a modern hospital, the best possible attention of orthopedic surgeons and physical therapists and psychologists and mental hygienists and nutritionists, without thought of the immense costs that are involved? Where else in the world are millions of dollars freely contributed by the people devoted to the establishment of cancer detection centers in great numbers, whose services are available for whatever the patient can afford to contribute? Where else in the world is money contributed voluntarily by the people to the advancement of scientific research—yes at times in sums which even the scientists cannot use effectively?

Associated with this pattern of the individual philanthropies are the new technics for meeting the costs of medical care involved in the highly intensified growth of voluntary hospitals and sickness insurance plans. The hospitalization plans now provide for hospitalization of some 30 millions of people who have enrolled, and the economist can see the reaching of a saturation point of perhaps 60 millions of people within the next decade. The voluntary nonprofit sickness insurance plans have already enrolled more than 6 million people, and the private voluntary sickness insurance plans claim between 23 and 25 million workers. The American people are the best insured people in the world, with some 75 million people enrolled and total assets of some 40 billion dollars. There was no compulsion or coercion in attaining this height. The people acted in response to the usual methods by which American industries, American philanthropies and indeed American institutions have been built.

That the health and welfare problems of our country which affect at one time or another every one of our people are primarily in the public domain as an essential function of government at some if not at all levels, no one need deny. But time has shown again and again that, unless that governmental function is stimulated and supplemented by the activity of the great private health and welfare agencies, the best interests of the people are not fully served. Governmental officials would be the first to admit this. But we must never forget that the strength of such private agencies is in their voluntary and independent nature. Without their identity, integrity and independence these private agencies could not exist. The emotion, the effort, the service that the American people give and give so willingly and freely through such organizations cannot be bought or compelled.

The point of view of those who would coerce rather than invite, who would direct rather than cooperate, who would compel rather than educate, need not necessarily be achieved only by making government the coercing force. Deceived perhaps by the magnificent results that have been achieved by many of the voluntary agencies, envious perhaps of the response of the people to some appeals and their failure to respond similarly to others, there are those who propose from time to time new types of organization of voluntary agencies which would place the compulsion not on the people who support and who receive the benefits from them but on the leadership of the agencies themselves. I refer particularly to a report of a survey of philanthropic agencies especially in the health field which suggested the establishment of a central group with a permanent directorate which all agencies would join and which would by their joining be compelled to accept the dictums of the central directorate as to the time when they would seek their funds, as to the methods by which they would seek their funds, as to the amounts of money which they could use and the manner in which their funds would be distributed. I venture to doubt that such a plan would produce the efficiency that this leadership seeks. I venture to doubt that the agencies which would be thus united would in the long run gain by their union. I have no hesitation in saying that those agencies would by this method bring about their own destruction.

Most serious of the losses involved by such technics would be the loss of the humanity which is fundamentally responsible for the great success that our philanthropic health agencies in this country have had up to now. Every individual who contributes now feels that he is helping another human being like himself. He sees the results of the aid that he gives, not in just any sick person, but in a child with poliomyelitis, a person with cancer, a worker crippled through the accident of industry, another human being who has been unable to resist the stresses and strains of our modern mechanized life and who has fallen by the wayside and who needs a helping hand. He gives not to an abstraction. He gives to one of his fellow men. . . .

When we think of totalitarianism I'm sure that we think of it only in terms of government. There may, however, still be even more dangerous forms of totalitarianism in industries, in machine politics, even in voluntary philanthropies. Individual agencies must maintain their independence from collectivism even as individual citizens must oppose a totalitarian government. In the industrial life of our nation there is an aphorism to the effect that one does not experiment with an established success. Our government, our resources, our philanthropies, our standard of living are today the envy of all the world. True, there are among us those who do not have all the benefits that derive to the majority; but it is not the American way to lower the majority to aid the indigent and the incompetent.

Although the American way is partly through government, it is supplemented to a very large extent by private philanthropy in aiding and assisting the less fortunate so that they may participate in and enjoy our standard of life. But even more important than that, it always has been and still is an essential function of private health welfare and humanitarian organizations to eliminate those things which cause the unfortunate minority. These things the nongovernmental organizations of America can do only if they maintain, as I am so certain the American people wish them to maintain, that identity, integrity and independence without which they cannot function and with which they can continue to carry on not only the work they do so well today but can accomplish in the future those results still so badly needed by the people in our country.

THE EPIDEMIOLOGY OF POLIOMYELITIS

Problems at Home and Among the Armed Forces Abroad

ALBERT B. SABIN, M.D.
Cincinnati

One of the most important and difficult jobs in science is to ask the right question of nature. The right question leads to the design of those experiments or tests which yield the pieces that are required to make a logical pattern out of an incomprehensible jigsaw puzzle. My paper will present more questions than answers, and I hope that among the many that have been asked those questions may be selected that will guide physicians to what must be learned in the future if the origin and evolution of epidemics of poliomyelitis is to be understood and if physicians are ultimately to know what, if anything, can be done to prevent them. From the point of view of public health the chief importance of poliomyelitis as a disease lies in its paralytic manifestations, and the main problem in the epidemiology of poliomyelitis concerns the cause or causes of the sudden appearance in certain parts of the world of large numbers of paralytic cases.

It has been stated that no circumstance in the history of poliomyelitis is so baffling as its change during the past fifty to sixty years from a sporadic to an epidemic disease.[1] While there are justifiable doubts regarding the adequacy of diagnosis and reporting in former years, the bulk of the evidence suggests that the epidemic outbursts, of the type which have occurred especially in the United States and a few other countries in the past thirty to forty years, are events that could not readily have been missed in the past. As a matter of fact it has been pointed out, and in my opinion correctly, that more adequate diagnosis and reporting are the effect rather than the cause of increased incidence. Nor can this recent origin of epidemics, although not of the disease, be doubted when it is realized that there are still large parts of the world, regardless of latitude, in which epidemics of poliomyelitis are as yet unknown. Another peculiar circumstance which may contain an important clue is that epidemics have occurred with greatest frequency and severity in the very countries in which sanitation and hygiene have undoubtedly made their greatest advances. In my opinion one of the most important problems in the epidemiology of poliomyelitis is the determination of the factors relative to the virus, host and environment, which are different in cities like New York, Chicago, Minneapolis, Los Angeles and Denver, among many others in the United States with histories of large outbreaks of the disease, and cities like Peiping, Tientsin and Shanghai, occupying approximately the same latitude in China, in which only rare sporadic cases have been recorded thus far, despite the presence in these cities for many years now of excellent western-trained physicians who could not have missed such outbreaks in the native population if they had occurred. Next in importance among the questions that may be asked with regard to the epidemiology of poliomyelitis

is why paralytic poliomyelitis, with only rare exceptions, remains practically dormant during more than two thirds of each year, appearing in only an occasional person, and then seems to explode during the late summer and early autumn? Still another circumstance, for which a correct explanation would reveal much regarding the character of the soil in which epidemics grow, is to be found in the many observations that when epidemics make their first appearance in large urban centers (whether thirty to forty years ago, as in certain cities of the United States, Sweden and Australia, or in the more recent past in a few cities of Japan) approximately 80 to 90 per cent of all the cases of paralysis occur in children under 5 years of age; whereas, in recent years in certain American, Swedish and Australian cities the age incidence has changed so that now as many or more children become paralyzed in the 5 to 9 year age group as in the group under the age of 5, and in many parts of the United States 25 to 33 per cent of all paralyzed patients are now in the 10 to 19 year age group.[2]

In order to be able to analyze these basic questions one must have certain information (*a*) about the natural history of infection with poliomyelitis virus in human beings, (*b*) about the reservoir of the virus in nature, (*c*) about the immunologic and invasive characteristics of the poliomyelitis viruses and (*d*) about the immune response of human beings to infection. It cannot be denied even by the most cynical that much has been learned in these fields through the patient and persistent labors of many investigators, even though many gaps in present knowledge still exist. I shall present rather briefly what, in my opinion, may be accepted as established without going into the details of the work on which the conclusions are based and spend more time on the points that I recognize and regard as having an important bearing on the epidemiology of the disease.

To begin with, what can be accepted as established about the natural history of infection in man with regard to how the virus is acquired by human beings, where it multiplies after it gets in and, finally, by what route and for how long it continues to be eliminated. It may perhaps be well to point out that the important extension of knowledge in regard to the presence of the virus in human stools during the past ten years, was not by itself responsible for a change in the concept of the nature of the human disease, since there was no indication that the virus in the stools did not have its origin in swallowed nasal and salivary secretions. Thus, Aycock[3] in 1941 was quick to point out that in pulmonary tuberculosis bacilli may be found in intestinal contents and that hemolytic streptococci from the respiratory tract may also be found in the intestines. However, the extensive studies in recent years on the distribution of virus throughout the human body in fatal cases have indicated that two systems, the alimentary tract and the nervous system, are predominantly attacked.[4] The virus was not found in the nasal mucosa, salivary glands or urinary bladder, to mention only a few of the important zones which were shown to be uninvolved. In the alimentary tract, the virus has now been demonstrated in the tongue and in the walls of the oropharynx, duodenum, ileum and colon. While in some cases the virus could be localized in the tissues of the upper as well as lower levels of the alimentary tract, at times it was limited to one or the other level. It also became apparent that the virus could be found in some portion of the tissues of the alimentary tract in practically all cases of human poliomyelitis, when a sufficient number of levels were tested. Furthermore, an analysis of the distribution of the virus in the entire body indicated that the virus did not get to the tissues of the alimentary tract by centrifugal spread from the central nervous system but rather that it was there as a result of primary localization and multiplication. It still is not known whether the multiplication of the virus, which, judging from its persistence in the stools, may continue for many weeks, occurs in the collections of nerve cells within the walls of the alimentary tract or in the nonnervous elements. The possibility has, of course, been considered that this pattern of virus distribution having been obtained in fatal cases may not represent what is actually occurring earlier in the disease. It may be said, however, that among the 13 fatal human cases studied in great detail by Ward and myself[4] a number of patients died within two to three days after the onset of the first "systemic" symptoms and only twelve to twenty-four hours after the first appearance of signs of involvement of the nervous system, but no significant difference was found in the types of tissues harboring the virus in these cases. The important question of whether or not the virus may be in the blood of human beings at some stage of the disease in sufficient concentration to offer a source of infection to blood-sucking insects was recently investigated with great care by Ward, Horstmann and Melnick[5] who were able to detect it in only 1 of 111 specimens taken from patients in early stages of the disease. This observation together with the earlier demonstration by Ward and myself[4] of the presence of the virus in a pool of the viscera in 1 of 7 fatal human cases tested, would suggest that occasionally small amounts of the virus may be absorbed into the blood from foci in which the virus is multiplying, but there is no indication that blood-sucking insects could acquire significant amounts of the virus from human beings.

The many studies which have now been carried out on the elimination of the virus from the human body indicate that it would have to originate either from the pharynx or the stools. Recently Howe, Wenner, Bodian and Maxcy[7] were able to demonstrate the virus in 43 per cent of oropharyngeal swabs taken from 23 patients during the first three days of illness, but in none of 13 swabs taken from the fourth to the ninth day of the disease. Horstmann, Melnick and

A.; Bodian, D., and Wenner, H. A.: Further Observations on the Presence of Poliomyelitis Virus in the Human Oropharynx, Bull. Johns Hopkins Hosp. **76:** 19 (Jan.) 1945.

Wenner,[8] following up this work, were able to recover the virus from the pharynx in only 2 of 19 patients (11 per cent) during the first week of illness and from none in the second week. The work of Horstmann, Ward and Melnick[9] on the persistence of the virus in stools after acute infection, indicated that the virus could be recovered in 70 per cent during the first two weeks, 50 per cent during the third and fourth weeks, 27 per cent during the fifth and sixth and 13 per cent during the seventh and eighth weeks. They found one stool positive at twelve weeks after onset out of 30 tested between the ninth and twelfth weeks and none of 23 after the twelfth week. The longest persistence on record was that reported by Lépine and his associates,[10] who recovered the virus from the stools of a child one hundred and twenty-three days after a mild abortive attack of poliomyelitis. In earlier studies by Ward and myself[10a] on a group of 20 patients during the first two weeks of illness, no virus could be recovered from the nasal secretions or the saliva and other secretions as they were expectorated over a period of three days. Ward and Walters[11] have recently reported that in extracts of cloth masks worn by children for periods of thirty minutes during the first three days of illness, they were able to detect the virus in 2 of 19 tested. It should be noted, however, that these patients were induced to blow and cough into these masks, activities which are not common for the poliomyelitis patient who, as a rule, does not have the nasal or tracheobronchial irritation which is present in infections affecting the upper part of the respiratory tract. It is also noteworthy that in a least 5 of Ward's patients from whom virus was recovered by throat swabs none was demonstrable in the masks into which they talked, blew, coughed and spit for one-half hour. It is fair to say that there is at the present time a difference of opinion as to whether droplets originating from the pharynx or the various means of dissemination which are possible for the virus in the stools play the dominant role in the spread of the disease.

One of the important issues in this respect is the extent to which infectious material present in the throat can under ordinary circumstances reach the environment in the form of droplets, which in the wet or dry state may subsequently be inspired by others. For as regards transmission by contact with hands and fomites, the opportunities for contamination from the stools would seem to be so much greater that the transitory presence of virus in the posterior pharyngeal wall would add little to this aspect of the problem. The interesting studies of Hamburger and his associates[12] on carriers of hemolytic streptococci seem to me to have considerable bearing on this problem. Their studies revealed first of all that those who are strictly throat carriers are relatively unimportant in the spread of infection, whereas those with strongly positive nose cultures are the dangerous carriers. They furthermore concluded that blowing the nose is the most important of the respiratory activities which result in dissemination of hemolytic streptococci under epidemic conditions and that contamination of the hands resulting from this act was probably the most important factor. However, extensive contamination of the hands by hemolytic streptococci was found in nasal carriers, but little in carriers with positive throat cultures but negative nose cultures. *Talking or breathing did not result* in the expulsion of significant numbers of streptococci, and relatively few were expelled by coughing. Sneezing usually resulted in the expulsion of a few streptococci in throat carriers but of many in nasal carriers, despite the fact that most of the droplets produced by a sneeze originate in the mouth. If one recalls, therefore, that the throat and not the nose or saliva is the source of virus in poliomyelitis, and that except for those with disturbances in swallowing the people who carry the virus of poliomyelitis do not usually have the nasal or tracheobronchial irritation which goes with infections of the upper part of the respiratory tract, one would not expect droplets to be a significant source of infection. Furthermore, if the aspiration of infected wet or dry droplets was an important source of infection in poliomyelitis, one would expect frequent invasion of the central nervous system from the nose by way of the olfactory pathway, which has now been amply demonstrated not to occur in human beings.[4] It may also be worth adding that while other droplet-transmitted infections have their own special prevalence during the late autumn, winter and spring, none has the seasonal incidence of poliomyelitis. For all these reasons, and quite aside from the fact that poliomyelitis virus is present in the pharynx for only relatively short periods of time, I am inclined to regard the various means of dissemination, both direct and indirect, which are possible for virus in the stools as playing the dominant role in the spread of the disease.

The circumstance of the stools being the most abundant source of the virus would have had little significance for the epidemiology of poliomyelitis, if it had not been established beyond doubt in recent years that experimental oral infection can be readily achieved. The controversy which existed less than ten years ago on this question was due to the fact that in the few reported successes infection by the olfactory pathway had not been ruled out and in the many reported failures the work was done usually in rhesus monkeys with virus that had been passaged for many years in the brains of monkeys. The controversy has been resolved by the demonstration that strains of virus of recent human origin could produce paralytic poliomyelitis by the oral route in chimpanzees[13] and cynomolgus monkeys[14] with considerable regularity without invading the central nervous system by the olfactory pathway. The importance of the strain of virus was particularly demonstrated in simultaneous experiments in my laboratory[15] in which a strain of recent human origin readily infected cynomolgus monkeys by the oral route while the old, virulent monkey-passaged M. V. strain of virus, with which almost all the unsuccessful tests had been reported in the past, failed to produce infection by the same technic in the same species of monkey. It may be worth noting here that there is no evidence now that infection by the oral route may not be possible even in rhesus monkeys, provided the proper strain of virus is used.

The abundance of the virus in human stools together with the demonstration of its presence in sewage[16] has, by analogy with the bacterial enteric infections, naturally raised the question of the possible role of flies and drinking water in the causation of epidemics of poliomyelitis. The first extensive work on flies in relation to outbreaks of poliomyelitis was done in 1941 by Paul and Trask and their associates,[17] who recovered the virus from flies trapped in rural areas close to a potential source of virus in the form of exposed recently evacuated human feces, and simultaneously by Ward and myself,[18] who recovered the virus from flies trapped in urban areas. We were able to demonstrate the virus in 7 of 12 samples from Cleveland and in 1 of 3 from Atlanta under cirsumstances in which no obvious potential source of the virus was in evidence within a short distance of the traps, which were put out in the backyards of the homes of patients who were away in the hospital and where the other probable virus carriers used good flush toilets. The flies which yielded positive results were either of the blowfly or housefly varieties. Three years later Ward, Melnick and Horstmann[19] carried this work a step farther during an outbreak in North Carolina by demonstrating that the food which was exposed to flies in homes of poliomyelitis patients became contaminated with enough poliomyelitis virus to be capable of establishing the infection in chimpanzees that ate it. The high incidence with which virus could be demonstrated in flies caught even in some of the cleanest and most sanitary urban areas cannot, it seems to me, be dismissed as an incidental finding without epidemiologic implications. It must mean that at some time or other, somewhere in the vicinity within a radius of 1 or more miles, the flies must have had the opportunity to pick up the virus. Even if the virus were to undergo no multiplication within the flies, and this has not yet been adequately investigated, it would seem clear that as long as myriads of flies have the proven capacity to acquire and transport the virus and the obvious capacity to contaminate human food with it—and in view of the fact that the possibility of infection with poliomyelitis virus by mouth is now established beyond doubt, it is not difficult to visualize the important role that flies may play in the dissemination of the virus during the summer and early autumn months. That is not to say that outbreaks of the disease during any season may not occur in the absence of flies or that in the combination of a source of virus, enough flies and an adequate number of susceptible persons one has all the ingredients to explain an epidemic of poliomyelitis; but it may indeed be suggested that the special seasonal character of the majority of poliomyelitis outbreaks may be related to the greater dissemination of the virus through the agency of contaminated flies, superimposed on the dissemination through normal human intercourse which has been shown to occur throughout the year, winter[20] or summer. Intimate human contact, while undeniably a factor in the year-round dissemination of the virus and in the so-called radial spread sometimes seen during outbreaks, does not by itself explain the recurrent summer epidemics of paralysis. With the present high incidence of the disease among children of school age in the United States, it is remarkable that, unlike certain other infections of childhood, the epidemics of paralysis occur during the very months when the children are away from school.

All this brings one back to another old question in the epidemiology of poliomyelitis, namely: do more people acquire poliomyelitis virus during the summer and early autumn months, or is there only a difference in the ratio between the number exhibiting the paralytic and inapparent, nonparalytic forms of the disease during the different times of the year? If there was only some way of answering this question by direct laboratory tests instead of by speculation, analogy or evaluation of probabilities, one could end the controversy between those who maintain that certain unknown changes in the host rather than increased dissemination of the virus, are responsible for epidemics and for the greater incidence of the disease in summer. Unfortunately, the methods available at this time are so cumbersome and expensive that one cannot undertake a mass survey of the number of people carrying the virus in a given community at different times of the year, as one might, for example, in the case of typhoid, dysentery or diphtheria; and the difficulties that would be encountered in trying to do it by determining the appearance of antibodies will become apparent, when the types of poliomyelitis virus and immune response to infection are discussed. Perhaps the only lead in existing data, that I know of, is to be found in the periodic tests carried out in Dr. Paul's laboratory[16b] on the same sewer line in New York since 1940. These data indicated that virus could be isolated from the sewage during September 1940 and then again in October 1941 simultaneously with a small increase in the number of clinical cases in the community served by this sewer line, but not during the other months. In further tests carried out by Dr. J. L. Melnick between 1941 and 1945, Dr. Paul has reported [21] that the results have always been negative during interepidemic times, although he believes that no final conclusions are possible until more work has been done with more sensitive methods of virus detection, particularly during seasons when the community is free from any increase in clinically apparent cases. Additional data of this sort may be one way to establish that outbreaks of the disease are due to the fact that larger numbers of people are being infected, unless it can be proved, as has been suggested by Kling and his co-workers,[22] that the virus may perhaps multiply in some protozoa in the stools and sewage away from the human body. Evans and Osterud [22a] have tested this hypothesis recently in a well-designed series of tests and have obtained negative results with various species of protozoa and different strains of poliomyelitis virus.

The idea that poliomyelitis is predominantly a water-borne disease has its foremost advocate in Kling [23] of Sweden. While it cannot be denied that water contaminated with virus-containing feces can theoretically be a source of infection, the available evidence is not convincing that the large epidemics occurring in American cities are related to water supply; [24] nor, if epidemics resulted from greater dissemination of virus by means of water, is there any known reason why they should occur during the late summer and early autumn and cease with the appearance of cold weather. The epidemics of dysentery occurring in the summer are usually correlated with flies rather than with water.

One cannot proceed in building the pattern of the epidemiology of any infectious disease without being certain of the reservoir of the causative agent in nature. For many years the assumption has been that the only reservoir of poliomyelitis virus in nature is the human being, and that it shares with certain other viruses like those of herpes simplex and measles the distinction of having no other natural host. The demonstration in recent years that the summer epidemic encephalitides are arthropod-borne and that their occurrence in man is only an accidental incident in the life history of those viruses, which may have a wide vertebrate and nonvertebrate distribution, has been responsible for repeated attempts to reexamine the position of poliomyelitis virus in nature. Despite the fact that poliomyelitis and encephalitis epidemics have occurred side by side in a number of instances during recent years, it has been clear that the epidemiology of the two diseases differs chiefly in that poliomyelitis continues throughout the year, while the summer virus encephalitides of man do not occur in the winter in the absence of the vector. Tests for poliomyelitis virus in various mosquitoes caught in the field, which have been carried out in the laboratories of Drs. J. R. Paul [17] and Thomas Francis,[25] have been negative. It was established a number of years ago that of the usual animals surrounding man young dogs, cats, rabbits, pigs, goats, lambs, calves, pigeons and chickens were not susceptible to poliomyelitis virus [1] and that it was, therefore, unlikely that they might be silent hosts. Pearson and his associates in Dr. Francis' laboratory [25] have recently reported negative results in their search for virus in the tissues or feces of a large variety of animals present in the environment of human cases of poliomyelitis. In the last few years this search has also extended to fish within polluted waters (unpublished studies carried out in 1941 by Ward and myself, and also Toomey and associates [26]) and, by Dr. J. L. Melnick, to birds like sea gulls above such waters [21] but thus far with negative results. The demonstration by Olitsky [27] and Theiler [28] of the many analogies between the spontaneous paralytic virus disease of mice and human poliomyelitis has led to speculation on a possible rodent reservoir of poliomyelitis virus that may be infectious for human beings. The murine poliomyelitis viruses are not pathogenic for monkeys, and there is no evidence that they are pathogenic for man. It would appear, therefore, that there is no reason at this time to modify the original assumption that the only reservior of poliomyelitis virus in nature is man. That does not mean that flies, certain monkeys or other as yet unknown animals may not get the virus under natural conditions from human sources, but it does mean that man is the ultimate reservoir.

There are a number of immunologic problems in poliomyelitis which undoubtedly have an important bearing on the epidemiology of the disease. Perhaps the most important of these is the problem of multiple immunologic types of virus. Although fifteen years have passed since the first data were published indicating that strains of virus isolated in Australia [29] and New York [30] were immunologically different from the standard monkey-passaged virus then in common use, and although this has been amply confirmed in a number of other laboratories in subsequent years, little if anything has been done thus far to correlate this important fact with the march of epidemics. While the data accumulated thus far are clear in indicating that there is more than one type of virus, it is not known whether the known strains fall into two, three or some indefinite number of distinct immunologic types. The determination of specific virus neutralizing antibody as an indicator of the occurrence of inapparent infection has proved a useful tool in elucidating the epidemiology of a number of virus diseases, notably yellow fever and the arthropod-borne encephalitides. For these and other infections it was established that, with few exceptions, the presence of these antibodies was a good index to previous infection with the virus. The same was at first believed to be true in the case of poliomyelitis. Thus, Harmon and Harkins [31] in 1936 collected from the literature the results of poliomyelitis neutralization tests on 512 normal serums, which study yielded the following significant figures: under 5 years of age,

37 per cent neutralized; 5 to 14 years, 48 per cent, and over 15 years, 73 per cent neutralized. This was believed to be in accord with the concept of widespread, inapparent infection, and because similar tests on serums from native adults in China,[32] the Fiji Islands,[33] Africa and certain other regions,[34] in which only sporadic cases but no epidemics were known to occur, were positive in approximately 90 per cent of the subjects it was assumed that the same type of virus was present all over the world and that infection was widespread even in regions where epidemics were unknown. However, between 1935 and 1939 a number of reports stated that there seemed to be no correlation between an attack of the disease, or the passing of an epidemic through a community, and the appearance of neutralizing antibody, as tested for the most part against a single standard passage strain of virus and occasionally also against some other more recently isolated virus. Thus it was found that 20 to 40 per cent of patients with the disease had antibodies when tested early after onset and that in general no definite increase in antibodies developed during convalescence. Of those who were without antibody early after onset, almost none acquired antibody during convalescence. The results of others, which were fully confirmed by his own studies in Australia, led so critical an investigator as Burnet[35] to conclude in 1939 that "poliomyelitis antibody is not a result of exposure to or infection by the virus of epidemic poliomyelitis." If this conclusion is correct the whole concept that poliomyelitis virus is as widely disseminated in one part of the world as in another, without reference to the occurrence of epidemics, can no longer be accepted without reservations, because it is based chiefly on the results of a small number of neutralization tests whose significance remains in doubt. In the last few years many more neutralization tests have been carried out on normal persons and on acute and convalescent serums of patients with poliomyelitis, using Armstrong's Lansing strain of mouse-adapted virus,[36] and in general the results were the same as those obtained with the monkey virus. This is reasonable because the Lansing virus is immunologically identical with the old standard M. V. strain which had been used in most of the monkey tests. And yet Paul and Trask,[37] and Howitt[38] as early as 1933 and Aycock[33] in 1942 pointed out that in certain patients antibody developed against recently isolated strains but not against the standard monkey passage strain. In 1941 Ward and I[39] had an opportunity to study the immunologic reactions in 1 of our assistants in whom poliomyelitis developed while she was working with a strain of virus of recent human origin. Virus recovered from the stools soon after onset of paralysis was proved to be immunologically identical with the strain of virus to which she was exposed. However, both the original virus and that recovered from the stools were found to be immunologically different from the standard M. V. strain of virus. Serum taken from this patient early after onset failed to neutralize both the monkey virus and the strain with which she was infected. However, the serum obtained during convalescence, although still unable to neutralize the monkey virus, readily neutralized the new strain to which she was exposed. In future studies on the immune response to infection it would seem wise to test the serums from each patient against the virus isolated from his own pharynx or stools and not to assume that a single type of virus is responsible for a single epidemic. It must be clear that until more work is done on the immunologic classification of the poliomyelitis viruses and on the immune response to infection, the available immunologic data will not be of much help in arriving at a clearer picture of the epidemiology of the disease.

Poliomyelitis has occurred among American troops in certain foreign countries, especially the Middle East,[40] the Philippine Islands and during the past summer Japan and North China,[41] in numbers and under circumstances that raise puzzling questions. If the disease were occurring among American soldiers (and this holds true also for the British and Australians[41a]) at a time when the more numerous native children all around them were also having paralytic poliomyelitis, the situation would not be so puzzling—but that was not the case.[42] Sporadic infections occur but outbreaks of any appreciable size apparently do not occur. A report on poliomyelitis in the Philippine Islands published ten years ago[43] stated that 16 of 17 patients with the disease at the Sternberg General Hospital in Manila were Americans. In 1945 there were 246 cases of poliomyelitis with 52 deaths among American troops in the Philippines according to the official reports received by the Office of the Surgeon General. Since the

42. One important exception to this occurred in the islands of Malta and Gozo in 1942-1943, when a large epidemic of poliomyelitis appeared for the first time in at least forty years. There were 426 paralytic cases among 271,359 civilians and 93.2 per cent of these were in children under 5 years of age. Only 4 cases occurred in Maltese adults (20 to 50 years of age) and none in the Maltese troops. However, 57 cases (all but 2 were paralytic) occurred in the troops of the United Kingdom (20 to 40 years of age), with an incidence of 2.5 per 1,000. Seddon, A. J.; Agius, T.; Bernstein, H. G. end of combat in the Philippines, poliomyelitis has been among the leading causes of death in American troops. Even though only the paralytic cases are reported from there, the incidence of poliomyelitis in American troops in the Philippines has been at least ten times as high as in the Army within the continental limits of the United States during the past two years. Actually, I believe that it is even higher because hundreds of cases which would have been diagnosed as nonparalytic poliomyelitis here are being diagnosed as dengue-like or sandfly-like fevers with pleocytosis under conditions which, in my opinion, would preclude the occurrence of both dengue and sandfly fever. And yet, checks of the surrounding native population revealed no outbreaks of poliomyelitis. Hernando and Alomia,[44] who reported small numbers of sporadic cases in Manila in 1933 and 1934, stated that epidemics of poliomyelitis were never observed in the Philippines. Doull, Hudson and Hahn,[45] reporting on the presence of neutralizing antibodies for poliomyelitis virus in the serum of 9 of 10 Filipinos from Cebu, stated that the disease was unknown there and that no evidence of sequelae were discovered. This past summer I had occasion to observe an outbreak of poliomyelitis among American marines stationed in the Tientsin area of North China. Four men died, 1 was severely paralyzed and at least 25 others had nonparalytic attacks. There was no evidence of an outbreak of poliomyelitis in the native population at the time, and Dr. Grice, a British physician in practice in Tientsin for twenty-five years, informed me that while he not infrequently saw paralytic poliomyelitis in children in the foreign colony he rarely saw the disease among the Chinese. The extraordinarily uncommon occurrence of poliomyelitis among the yellow races living in North China was also reported by Zia[46] in 1930. The 1 isolation of poliomyelitis virus reported from Peiping in 1941 by Yen and Hsu[47] was from a white girl. Scott[48] also commented on the rarity of poliomyelitis in China.

In Japan this year the incidence of poliomyelitis in American and British forces, while considerably less than that in the Philippines, was still higher than in the Army within the continental limits of the United States even if one does not count the large number of patients exhibiting the aseptic meningitis syndrome, in the majority of whom, in my opinion, the most likely diagnosis was nonparalytic poliomyelitis. Two strains of poliomyelitis virus were isolated in Dr. Paul's laboratory from stools of some of these patients which I sent from Japan Paralytic poliomyelitis is still an uncommon disease in Japan, but small epidemics have occurred in the Osaka-Kobe area between 1938 and 1942, and in these about 90 per cent of the cases occurred in children under 5 years of age (communication from Professor M. Kasahara of the Imperial University of Osaka).

This relatively higher incidence of poliomyelitis among foreign troops stationed in areas in which the clinical disease is relatively infrequent in the native population may be due to the fact that the virus is actually more widespread than in the United States and also that the immunologic types of virus prevailing there may be different from those to which these men had been exposed in their infancy and childhood. If it is suggested that the prevailing viruses are so widely disseminated in these countries that infection is acquired by almost every one early in infancy, then it must be asked why that infection is so inapparent and accompanied by so little paralysis? Is it possible that there is a time in infancy, and it would have to be less than 1 year of age, when infection with poliomyelitis virus is predominantly inapparent and results in lifelong immunity? The reason for setting this time at less than 1 year of age is based on the fact that when epidemics of poliomyelitis make their first appearance in countries where the disease had formerly been seen infrequently almost 90 per cent of the paralytic cases occur in children between 1 and 5 years of age. If there is such a hypothetic period of grace, one would have to suppose that immunity to all prevailing immunologic types is acquired during that short period of time. Does it follow, then, that epidemics begin to occur in a country when large numbers of children fail to acquire the poliomyelitis viruses during that important phase of their life? On the other hand if one assumes, as suggested by Burnet,[49] that "the major factor responsible for the epidemic appearance of paralysis is the occurrence of biologically irrelevant mutation in the virus to an unduly invasive type" and that such viruses have not yet made their appearance in countries like the Philippines or North China, how is one to account for the different behavior of the infection in the native populations and the foreign troops stationed there? If the first appearance of epidemics were due to the introduction of a new immunologic type of virus, one would not expect to find 80 to 90 per cent of the paralytic cases among children under 5 years of age, but rather would expect them to be more widely distributed through the population. And yet, in the recent severe epidemic in Malta,[42] which occurred after a quiescent period of at least forty years, paralysis among the native population appeared almost exclusively (93 per cent) in children under 5 years of age, while the adult troops of the United Kingdom in the area succumbed in relatively large numbers (2.5 per 1,000). To account for the occurrence of 422 paralytic cases in children under the age of 5 among a total (all ages) native population of 271,359 on an immunologic basis, the possibility must here be considered that a type of virus was involved to which the adult Maltese, but not the adult United Kingdom troops, were immune and also that this type of virus had had limited or no dissemination in Malta during the preceding five years.

In conclusion I wish to reiterate what I regard as perhaps the most important question: Why did paralytic poliomyelitis become an epidemic disease only a little more than fifty years ago, and as such why does it seem to be affecting more and more the countries in which sanitation and hygiene, along with the general standard of living, are presumably making the greatest advances, while other large parts of the world, regardless of latitude, are still relatively unaffected? If I have left the reader somewhat bewildered and with the impression that physicians do not know the answers to these and other basic questions regarding the origin and evolution of epidemics of poliomyelitis, I apologize, but I must confess that it was precisely what I intended to do.

ADDENDUM

Public health officers and other physicians frequently seek the advice of "poliomyelitis experts" on what to do during an epidemic. These "experts" are as a rule reluctant to supply even guiding principles because, as has been pointed out in this communication, much remains to be learned about the cause of epidemics and the dissemination of the virus. However, there are certain reasonable measures which may be taken during epidemics with a view to minimizing the chances of infection, even if there is no evidence or assurance that these measures will stop an epidemic of poliomyelitis "cold" as effectively as will the advent of "cold" weather.

Until information to the contrary becomes available, the following guiding principles may, in my own opinion, be offered to physicians:

A. More virus is being disseminated in a community during an epidemic than at other times.

B. Poliomyelitis virus is present for a short time in the throat and more frequently and for a longer time in the intestinal tract and stools of certain apparently healthy people as well as of acutely paralyzed patients during an epidemic.

C. From these sources of infection the virus may be transmitted to others by intimate contact, contaminated hands and fomites. There is no evidence that the virus is ordinarily present in the nose or that droplets emitted from the respiratory tract play a significant role, if any, in the dissemination of the virus.

D. During an epidemic the "filth" flies can be contaminated with the virus, which they can deposit in infective amounts on food, and consumption of such contaminated food can produce the disease.

With these guiding principles in mind, the following opinions are offered on questions which most frequently come up for consideration:

1. Measures designed to minimize spread by droplet infection, such as the closing of movies and churches or the refusal to admit patients with poliomyelitis on general hospital wards are not warranted.

2. Measures designed to diminish the chances of transmission by contact during intimate play of children whether out of school or in school are reasonable and warranted. Public playgrounds and swimming pools should be closed. Schools may be opened or should remain closed depending on whether the avoidance of contact among children can be enforced better in school or out of school. The mere presence of a large number of children in a single room cannot be regarded as conducive to transmission of the virus, while playing, shaking hands or using a common toilet without adequate washing of hands may be. Parents should have the right to decide for themselves whether or not they wish to send their children to school during an epidemic. Avoidance of strenuous physical exercise during an epidemic or in cases of known, intimate exposure is reasonable.

3. Measures designed to minimize contamination of food by flies, whether in stores or in homes, are reasonable and warranted.

4. Measures aimed at the mass destruction of flies by the spraying of DDT from airplanes or other moving vehicles on whole towns after an epidemic has appeared is of doubtful, if any, value.

5. Measures taken to prevent flies from breeding in or having access to the sludge beds and other parts of metropolitan sewage disposal plants and creeks containing raw human sewage are reasonable and warranted.

6. Disposal of stools from patients with poliomyelitis in homes or hospitals into the sewer system without previous disinfection of the virus is not contraindicated, because during an epidemic the sewer system is contaminated with greater amounts of virus by the many persons who are infected and do not know it. Where no flush toilets are available, the stools may be emptied in the privy used by the rest of the family, but special precautions should be taken to prevent access of flies to it.

7. Patients with poliomyelitis can be admitted on general hospital wards but should be treated with so-called typhoid technic. Bedpans used only for 1 patient need only be washed after the contents are emptied into the sewer system; if they are used interchangeably they should be sterilized by live steam. This typhoid technic should be applied for at least four weeks dating from the onset of the first "systemic" symptoms.

8. Bedsheets, towels and other laundry during poliomyelitis epidemics may be regarded as potentially contaminated, and advice in regard to the wearing of gloves and washing of hands by workers handling such laundry before it is washed is reasonable and warranted.

9. Isolation in the home of patients whose disease is diagnosed as poliomyelitis is indicated for at least two weeks and is reasonable for a period of four weeks dating from the first onset of symptoms. The children of such households and older members who may be engaged in the handling of food in stores or restaurants, or whose occupations may bring them into intimate contact with children, should remain at home for a period of at least two weeks. The same procedure may be advocated for other children who may have been exposed in intimate play with members of an infected household. While it is unquestionably true that isolation at best can control only an indefinite fraction of those who may be disseminating the virus, it is nevertheless reasonable to attempt to protect a small number of persons, even if the risk for the community at large may not be affected appreciably by such a measure.

Finally, it is necessary to repeat that all these measures are advocated not with the idea that they will stop an epidemic but rather in the belief that in as far as they are carried out diligently at least some persons may escape infection who might otherwise have become paralyzed.

THE BULBAR FORM OF POLIOMYELITIS

I. Diagnosis and the Correlation of Clinical with Physiologic and Pathologic Manifestations

THE MINNESOTA POLIOMYELITIS RESEARCH COMMISSION
Minneapolis

Despite the fact that most of the deaths from acute poliomyelitis are commonly conceded to result from involvement of the medulla oblongata and immediately contiguous brain centers, comparatively little special attention has been given to this form of the disease by either clinical or laboratory investigators. This obvious neglect of one of the most important aspects of the problem of poliomyelitis can be attributed, in part at least, to two erroneous assumptions. The first of these is that the incidence of the bulbar form of poliomyelitis is low, the 6 per cent figure of Wickman [1] still being relied on by many authorities as a basis of estimation. The second is that there is little to offer the victims of this form of the disease in the way of therapy. It is not unusual, for instance, to hear the glib statement that patients with bulbar involvement are divisible into but two groups, those who will recover spontaneously without any therapy and those who are so severely afflicted that they will die no matter what form of treatment is applied.

Because our experience on the neurologic and pediatric services of the University Hospitals during the recent epidemic in Minnesota (largest in the United States in 1946) was quite at variance with these views, we wish to call renewed attention to the overall importance of the bulbar form of poliomyelitis, emphasizing in particular the need for earlier recognition of pathognomonic signs and for prompter and more intensive treatment. The incidence of bulbar involvement among the unselected cases of the disease in patients admitted to our special emergency clinic, with or without spinal manifestations, was 23 per cent in children under 16 years of age and even higher in patients beyond this age. That symptomatic treatment can be to some avail in many cases of severe bulbar involvement is indicated in an accompanying paper which deals with therapy. These two communications on the general clinical aspects of the subject will be supplemented by a series of detailed reports to be made by our colleagues, who have investigated different phases of the problem.

SYMPTOMATOLOGIC AND PATHOLOGIC CLASSIFICATION OF BULBAR POLIOMYELITIS

A detailed study of symptomatology as related to special functional disturbances observed during life and pathologic changes found post mortem in fatal cases led to a comprehensive classification, which will be reported elsewhere in detail by two of us.[2] While there is obviously a considerable degree of overlapping between the various categories as far as many individual cases are concerned, early recognition of signs or symptoms on the basis of their site of origin has often proved to be of distinct value in both diagnosis and treatment. For the sake of simplicity in terminology, the word bulbar has been used with some degree of license to denote involvement of the entire brain stem, including the medulla, pons and midbrain.

The classification finally evolved to include all cases of the bulbar form of poliomyelitis was the following: (1) those in which the nuclei of the cranial nerves are involved—(*a*) upper cranial nerve group and (*b*) lower cranial nerve group; (2) those in which the autonomic centers are affected—(*a*) respiratory center group and (*b*) circulatory center group; (3) those in which there is combined bulbar and encephalitic involvement—(*a*) diffuse encephalitic group and (*b*) focal encephalitic group, and (4) those in which bulbar and upper spinal involvement are combined.

1. BULBAR-CRANIAL NERVE NUCLEI GROUP

The clinical symptoms of the group of cases in which the nuclei of the cranial nerves are involved has been long recognized in bulbar poliomyelitis. These symptoms are readily noticed and easily explained. They result predominantly from involvement of the motor nuclei of the cranial nerves.

(*a*) *Upper Cranial Nerve Group.*—The upper cranial nerve nuclei group includes involvement of fifth, sixth, seventh and eighth cranial nerves as well as the ocular nerves. This produces the syndromes known as polioencephalitis superior and polioencephalitis inferior of the older literature.[3] For convenience all the various ocular manifestations of bulbar poliomyelitis have been placed in this group, although some of these manifestations are not related directly to the oculomotor nuclei. Isolated ocular neural palsies as well as total external ophthalmoplegias have been described in poliomyelitis.[4] Pupillary disturbances, including Horner's syndrome and hippus, have also been reported. Apparently any combination of palsies may occur. Although ocular manifestations were not common in the patients seen at the University Hospitals, 1 patient suffered a complete external ophthalmoplegia with bilateral ptosis. His pupillary responses were normal. Choked disk was observed on one occasion in a patient who was in a respirator.

Disturbances of mastication result from damage to the motor portion of the fifth cranial nerve. Palsies of the fifth nerve may be unilateral or bilateral and may involve part or all of the muscles supplied by the fifth nerve. On examination the patient may be unable to close his mouth, but in less severe cases it may be necessary to test the movements against resistance. In unilateral lesions of the fifth nerve the jaw may deviate spontaneously when the patient opens his mouth, while at other times the action of the pterygoid muscles must be tested by sideward deviation of the jaw against resistance. Palsies of the fifth nerve were observed on a few occasions in the patients considered in this paper.

Paralysis of the facial nerve was observed fairly frequently among the poliomyelitis patients. It was observed with sufficient frequency to make it unreliable

in the differential diagnosis between poliomyelitis and Guillain Barré's disease. At times the entire area of distribution of the facial nerves was involved, and at other times the weakness was limited to the upper or lower part of the face.

Bilateral deafness and also vestibular disturbances have been reported in the literature on poliomyelitis.[5] The only symptoms referable to the eighth nerve observed in the University Hospitals' patients were vertigo and vomiting. These were present in a few instances and were distressing though transient, lasting only twenty-four to forty-eight hours. Nystagmus was observed in several patients.

The involvements of the cranial nerves discussed so far hold no threat to the life of the patient with poliomyelitis. They may, however, be annoying, and the residuals may produce definite handicaps. They are of importance, nevertheless, because they make the physician alert to the possibility of the implication of more vital centers. If the symptoms remain strictly limited to the upper group of cranial nerves the prognosis for life should be good.

(*b*) *Lower Cranial Nerve Group.*—Involvement of the nuclei of the lower cranial nerves, particularly the tenth, affords a definite threat to the life of the patient with bulbar poliomyelitis. This nerve in conjunction with the eleventh and twelfth is essential for consummation of the act of deglutition. Brahdy[6] reviewed the function of deglutition in relation to poliomyelitis and came to the conclusion that swallowing is initiated by movement of the tongue forcing the bolus of food through the isthmus faucium. The mylohyoid muscle then forces the bolus into and through the pharynx, the larynx and nasopharynx being shut off from the pharynx. To accomplish this requires innervation of the soft palate, faucial pillars, vocal cords, elevators of the larynx and depressors of the epiglottis. These functions are subserved by the cranial nerves previously named. Peristaltic movement continues the passage of food down the esophagus. Brahdy described the following four types of difficulty in swallowing in poliomyelitis: regurgitation through the nose, accumulation of food or fluid in the pharynx, regurgitation of food from the esophagus and cough due to failure to shut off the larynx.

Patients with bulbar poliomyelitis may have any of these symptoms from involvement of the lower cranial nerves, especially the tenth. On examination, one notices nasal speech and failure of equal movement of the soft palate. There is puddling of saliva in the throat, the patient being unable to handle his secretions by swallowing. These secretions may be so profuse that one is forced to think of the possibility of excessive secretion of saliva. In some, the voice is hoarse due to paralysis of the vocal cords. Laryngeal stridor may be present. Weakness of the tongue may be unilateral or bilateral and may impair the movement of food through the mouth and impede the expectoration of saliva. Weakness of the sternocleidomastoid and trapezius muscles occurs but is not of much immediate importance. Difficulty in swallowing was the commonest sign of cranial nerve palsy in the group of patients with bulbar poliomyelitis at the University Hospitals. Brahdy[6] recorded difficulty in swallowing in 87 of the 123 cases of bulbar poliomyelitis.

Considerable importance must be placed on lesions of the tenth cranial nerve because, as has been noted, such lesions furnish an immediate threat to the life of the patient with bulbar poliomyelitis. With the inability to swallow there is the constant tendency toward pooling of saliva and food in the pharynx. This accumulation produces an obstruction to the airway. A further threat to the airway results from the aspiration of fluid into the larynx or from reflex spasm of the glottis. Lesions of the tenth nerve may also produce impaired innervation of the vocal cords. This may manifest itself by a warning stridor or by a rapid abductor paralysis of the vocal cords with sudden asphyxia and death. Direct laryngoscopic examination of a patient in such an asphyxial crisis showed the vocal cords to be approximated in the midline.[2] Immediate insertion of a Mosher lifesaving tube in that instance reestablished the airway.

Interference with the airway by the accumulation of fluid in the throat has been combated by postural drainage and by suction. This, however, will not prevent approximation of the vocal cords in the midline. The importance of maintaining an adequate airway is apparent when it is remembered that any period of anoxia, whether acute or chronic, can do irreparable damage to nerve cells which are already suffering from an inflammatory disease. A further complication from occlusion of the upper airway is the production of acute pulmonary edema. The following cases are typical examples of involvement of the nuclei of the lower cranial nerves.

Case 1.—C. S., a boy aged 7 years, was admitted to the University Hospitals on July 31, 1946. The past history was not relevant except for a tonsillectomy which had been performed July 12. Two days before the patient's admission general malaise, nausea, vomiting and fever developed. The day before admission he had difficulty in swallowing, and a nasal twang was noticed when he spoke. Abnormal ocular movements were noted by his mother.

On examination he appeared acutely ill. The cranial nerves were extensively involved. The ocular movements were incoordinated, and a horizontal nystagmus was present to both the left and the right. The mouth could not be opened. The masticatory muscles were tender. Weakness of the right facial muscles was present. He was unable to swallow, and his voice was nasal in character. The tongue would not protrude, and he could not hold up his head. The reflexes in his extremities were normal, and no weakness of the arms or legs was noted. The tremor of his hand was violent, and the neck and back were rigid.

The cerebrospinal fluid contained 149 cells per cubic millimeter, 85 polymorphonuclear and 64 mononuclear. The protein level was 84 mg. per hundred cubic centimeters.

The temperature on admission was 103.2 F. Shortly after admission a large amount of blood-stained mucus was aspirated from the pharynx. However, the color of the patient was good at the time. Restlessness and disorientation developed rapidly. About eight hours after admission the boy was cyanotic and frothy mucus was coming from his nose and mouth. He died suddenly.

At autopsy the lungs were heavy and edematous, the right weighing 350 Gm., the left 250 Gm. There was frothy, orange to pink fluid in the trachea and bronchi. The cut surface dripped edematous fluid. The microscopic examination confirmed the gross observation of massive pulmonary edema.

[6] Brahdy, M. B., and Lenarsky, M.: Difficulty in Swallowing in Acute Epidemic Poliomyelitis, J. A. M. A. **103:** 229 (July 28) 1934.

CASE 2.—N. M., a farmer aged 33, first noticed excessive salivation and a mild sore throat about one week prior to his admission to the hospital. During this period, in spite of his malaise, he continued to work and to do the chores around his farm. Two days before admission there developed a severe headache, a backache and a stiff neck. He came to the hospital because of an abrupt appearance of dysphagia and a nasal quality to his speech.

When seen his temperature was 102 F., the pulse rate, 110 and the respiratory rate 24. He was acutely ill. There was an involvement of the fifth and seventh cranial nerves on the right side and a paresis of the ninth and tenth nerves bilaterally. Muscle function was otherwise intact. A spinal puncture revealed 81 cells per cubic millimeter, with 24 polymorphonuclears.

Shortly after his admission hoarseness developed, with increasing difficulty in phonation and swallowing. Saliva was accumulating in the hypopharynx. A tracheotomy was performed to provide an adequate airway, and oxygen was administered through the tracheotomy tube. His temperature dropped slowly. During the next few days, the patient was a little restless and was confused at times. A great deal of mucus was removed by suction through the tracheotomy tube. His cranial neural involvement appeared to remain stationary. By the seventh hospital day he began to swallow a little. The next day he was able to take sips of water. His voice remained hoarse and squeaky. Improvement continued, and on the twenty-third hospital day the administration of oxygen was discontinued. On the twenty-fifth day the tracheotomy tube was removed. The patient was discharged on the thirty-first hospital day, at which time he had completely recovered.

Paralysis of the nuclei of the lower cranial nerves can produce death by occlusion of the airway. The prognosis is good if an adequate airway is maintained and if the pathologic process remains limited to the cranial neural nuclei without involvement of the central autonomic system. Symptoms of such involvement are of serious prognostic import.

2. BULBAR-CENTRAL AUTONOMIC GROUP

It has been frequently observed in the past that patients may have extremely serious forms of bulbar poliomyelitis with only minimal evidence of involvement of the nuclei of the cranial nerves. Several authors [7] have suggested that death in these cases must be due to involvement of vital centers. McMillan [8] has noted a lack of relationship between the temperature and the pulse rate. In some of his patients the temperature rose rapidly as high as 110 F. before death. In others the temperature remained around 102 F. or less, while the pulse rate reached 150 and the respiratory rate was 50 per minute before death. A reference has been noted to an article in a foreign journal [9] on the function of the autonomic nervous system during the acute stage of poliomyelitis. Because of wartime delay of shipping this article is at present unavailable to us. As far as we have been able to determine, the recent communication by Brown and Baker [2] is the first correlation of clinical evidence of disturbed central autonomic function in poliomyelitis with the pathologic lesions and the recent advances in neuroanatomy and neurophysiology. Lesions in the reticular formation have been mentioned previously [10] but without clinical correlation. In the Minnesota poliomyelitis epidemic of 1946 a number of patients were seen with evidence of only mild paralyses of the cranial nerves but with severe disturbances of autonomic functions. These cases were studied clinically and pathologically. The observations have been reported in a recent communication.[2] The cases reported in the following groups are further examples of this correlation.

(*a*) *Bulbar-Respiratory Center Group.*—In our experience, symptoms of involvement of the respiratory center in the medulla have come on a number of days after the onset of pareses of the cranial nerves. The patients in this group have shown some palsies of the cranial nerves and also some evidence of circulatory and encephalitic involvement. However, the outstanding symptoms have been respiratory. During the course of the illness there develop irregularities of rhythm and depth of respiration. Respirations tend to be shallow, and there are prolonged intervals between inspirations. Following this, prolonged periods of apnea occur, and finally respirations cease. These respiratory symptoms have occurred despite strong intercostal muscles and a strong diaphragm. During and previous to the development of respiratory symptoms these patients are extremely anxious and apprehensive. They require frequent reassurance to calm them. There are periods of confusion. These symptoms frequently are caused by a hypoxia and may be present before the appearance of cyanosis. The use of the oximeter may aid in the detection of these early hypoxic states. Ultimately the temperature and pulse rate trend upward. The blood pressure may be elevated or may fall to shock levels terminally. In fatal cases there develops increasing cyanosis which defies attempts at adequate oxygenation. At necropsy there is pronounced hemorrhagic pulmonary edema.

Microscopic examination of the medulla oblongata at the level of the inferior olivary body has shown extensive inflammatory necrosis bilaterally in the ventral reticular substance. Pitts,[11] with Magoun and Ranson,[12] on the basis of stimulation experiments in cats, located the inspiratory and expiratory centers for respiration at the level of the inferior olivary body. The inspiratory center was found to be dominant and was located ventrally in the reticular substance. The expiratory center overlaps the inspiratory center and extends more dorsally and cephalad. The location of the respiratory center in cats corresponds almost exactly with the areas of inflammatory necrosis seen in patients who have died of central respiratory failure. Some patients with less severe symptoms involving the respiratory center recovered but required temporary use of the respirator in some instances. In general, involvement of the respiratory center is of serious prognostic import.

CASE 3.—D. T., a boy aged 13, was admitted to the pediatric service of University Hospitals on Aug. 17, 1946. He had become ill three days previously with sore throat, headache and an elevation of temperature to 101 F. He was listless and tired until the day of admission, when he suddenly began to vomit and his temperature rose to 103 F. At this time a nasal tone of voice was noticed, and he had difficulty in drinking water.

On admission he appeared acutely ill and decidedly lethargic. His blood pressure was 118 systolic and 80 diastolic. Slight weakness of the left facial muscles and paralysis of the right side of the palate with deviation of the uvula was evident. He had difficulty in swallowing and speaking, and large amounts of mucus were present in the posterior pharynx. Examination of the spinal fluid performed at another hospital was reported to have shown 27 mononuclear cells per cubic millimeter.

The facial weakness and difficulty in swallowing progressed during the first few hours in the hospital. The boy became nearly aphonic. Six hours after admission a tracheotomy was performed. He continued to be toxic and lethargic. His temperature rose to 106 F. on occasion during the next few days. The blood pressure fluctuated, rising to 150 systolic and 100 diastolic at times. On the fifth hospital day the patient became cyanotic with respiratory distress; oxygen was administered directly into the tracheotomy tube. His respiratory rate was irregular, and he had periods of apnea which lasted for one to three minutes. On the sixth hospital day he ceased breathing. A 25 per cent solution of nikethamide and artificial respirations were used, and irregular respirations were again established. The respirator was used only for the apneic periods, as the patient worked against it when breathing. On the seventh day, he became comatose, the temperature rose to 104 F. and the blood pressure fell to 80 systolic and 50 diastolic. The respirator was used continuously at first, but by the tenth day he could be out at intervals and gradually improved. By the thirteenth day he could take sips of water. The tracheotomy tube was removed on the thirty-fourth day without incident.

On December 13 he still showed left facial paresis and mild palatal involvement, but there were no other residual symptoms of consequence.

(*b*) *Bulbar-Circulatory Center Group.*—Symptoms of involvement of the circulatory center may be seen developing concomitantly with symptoms of palsies of the cranial nerves. In a few instances the circulatory symptoms are the predominant part of the clinical picture and those involving the cranial nerves are minimal.

The clinical symptomatology which results from involvement of the central control of circulation often is quite characteristic. The patient's lips are a deep cherry red, and the skin has a flushed, florid appearance. The pulse rate is extremely rapid, ranging between 150 and 200. It is often irregular and at times difficult to palpate. The blood pressure is low and later becomes unobtainable. The pulse pressure is small even with relatively normal systolic levels. The difference between systolic and diastolic pressure is often as little as 10 mm. of mercury. Terminally the skin is cold and clammy and has a mottled cyanosis. Hyperthermia is noted at that time, and the respirations tend to be shallow. These patients are apprehensive, anxious, restless and confused. The heartbeat is inaudible before respirations cease. Circulatory symptoms of milder intensity are observed in patients classified in the other groups of bulbar poliomyelitis. As long as symptoms referable to the circulatory center are present the prognosis remains guarded.

At necropsy the lungs are the site of severe hemorrhagic pulmonary edema. Sections through the medulla at the level of the inferior olivary body reveal intense inflammatory necrosis bilaterally within the dorsal reticular substance just below the floor of the fourth ventricle.[2] The dorsal motor nucleus of the vagus nerve and the nucleus ambiguus show almost no involvement.

Wang and Ranson [13] conducted experiments in cats using the Horsley-Clarke stereotactic instrument to study the effect of stimulation of the brain stem on blood pressure. They obtained decided pressor responses from the dorsal reticular substance of the medulla just beneath the floor of the fourth ventricle at the level of the inferior olivary body. Depressor responses were more diffuse and were located in the dorsolateral and, to a less degree, the ventromedial reticular substance of the medulla oblongata at the level of the inferior olivary body. They also observed mild pressor responses in the tegmentum of the pons. From this work it seems warranted to consider the dorsal reticular substance of the medulla oblongata at the level of the inferior olivary body an important area in the control of vasomotor responses. This area was the site of intense inflammatory necrosis in patients with bulbar poliomyelitis who died of circulatory collapse. Intact vagal nuclei would seem to rule out the vagus nerve as an essential part of the clinical picture.

Case 4.—Y. L., a white girl aged 16, first became ill Oct. 7, 1946, at which time there developed headache, stiffness of the back and neck and some nausea and vomiting. The following day she noticed difficulty in swallowing and was sent to the hospital by her physician.

On admission the patient revealed only a mild degree of dysphagia, a slightly stiff neck and some weakness of the left deltoid muscle. Her temperature was 104.6 F., and her pulse rate was 24. She was coughing up large amounts of mucus. Because of the bulbar symptoms a tracheotomy was performed shortly after admission. During the next twenty-four hour period, the patient became somewhat more restless. An oxygen-helium mixture was administered through the tracheotomy tube. Her pulse rate gradually rose to 150, and her respirations became slightly shallow. Her blood pressure varied between 108 systolic over 88 diastolic and 30 systolic over a questionable diastolic reading. Toward the end of the second hospital day the patient had become very restless. Her pulse was feeble, rapid and irregular, and her blood pressure was difficult to obtain. In spite of all supportive measures, the respirations became shallow and the patient expired after a twenty-six hour hospital stay.

3. BULBAR-ENCEPHALITIC GROUP

Encephalitic symptoms are not infrequently seen in patients with bulbar poliomyelitis. Lemmon [14] reported cerebral symptoms in 17 of 49 cases he studied. Because of the frequency with which these symptoms are observed in bulbar poliomyelitis, their appearance should lead one to consider a tentative or expectant diagnosis of bulbar poliomyelitis even in the absence of objective evidence of palsies of the cranial nerves. This presumption was usually verified in our cases by the subsequent course of the disease. This was true of the symptoms we have classified in the diffuse encephalitic group but was not as true of those in the focal encephalitic group.

(*a*) *Diffuse Encephalitic Group.*—The following symptomatology is observed frequently among patients with bulbar poliomyelitis and in our experience is universally present among the more severely ill patients. The presence of these symptoms should alert one to the possibility of a bulbar involvement even in the absence of objective signs of cranial neural pareses. These patients show great anxiety and apprehension. They are keenly aware that something serious is wrong with them and frequently feel (often correctly so) that they are going to die. They require repeated reassurance that things are progressing satisfactorily. *Ideas come* to them with unusual rapidity, and *minimal* stimuli produce rapid responses. Some patients comment on the fact that ideas race through their minds. In the motor sphere these patients show quivering, trembling, twitching and jerking of the facial muscles and to a lesser degree of the extremities. The face is flushed and there is a tremor of the hands. All movements are extremely rapid as a part of the general hyperactivity. These patients have a pronounced urgency about getting rid of pharyngeal collection of fluids, about having the pillows rearranged or about having the tracheotomy tube readjusted. Their urgency is indicated by snapping of fingers, quick movements of the head or extremities or sudden sitting up in bed. Many of these patients are unable to sleep and remain awake several days and nights before their hyperactivity subsides. In the fatal cases confusion becomes prominent and is often followed by lethargy, coma and death. At first we considered some of these bulbar patients to be neurotic, but further experience taught us to respect their premonition that things were not going well.

[14] Lemmon, G. B., Jr.: An Analysis of Forty-Nine Cases of Acute Anterior Poliomyelitis, Pennsylvania M. J. **45**: 1039, 1942.

Prolonged somnolence has been reported by Tilney.[15] This occurred once among the adult patients observed at the University Hospitals, but was more commonly observed in the children.

In many patients, especially those in respirators, a typical toxic confusional state appears about one week after the onset of the illness and lasts about a week. These persons develop fixed ideas and stubbornness *which* gradually merge into paranoid projections about members of the nursing or medical staff. These ideas are occasionally replaced by obvious misinterpretations, hallucinations and irrationality. Contact with reality can be restored in some persons by lighting the room more brightly, by permitting a view of the street outside the window or by a visit from a close member of the family.

Although many patients with bulbar poliomyelitis showed the clinical [illegible] indicative of cerebral involvement, [illegible] actually had inflammatory changes within the cerebral hemispheres. However, it was noticed that the cerebral symptoms would frequently disappear after measures were taken to insure adequate oxygenation of the patient. This was accomplished by tracheotomy, suction or oxygen under positive pressure by mask or tracheotomy. This led to the conclusion that many of the cerebral symptoms seen in bulbar poliomyelitis were secondary to cerebral anoxia rather than to direct involvement of the brain by the virus. In poliomyelitis the common factors that may result in deficient oxygenation of the blood are as follows: obstruction of the air passages by *secretions or* by *paresis* of the vocal cords; failure of the peripheral or central respiratory mechanism; failure of circulation; pulmonary complications, especially atelectasis or hemorrhagic pulmonary edema, and failure of the mechanical devices used in treatment. The appearance of the encephalitic symptoms, therefore, serves as a warning to reexamine these patients for the various causes of anoxia. Persistence of the symptoms despite attempts to improve the oxygenation is of serious prognostic import. The following case is an example of the encephalitic group of bulbar poliomyelitis.

Case 5.—K. M., a man aged 36, first had abdominal pain on Aug. 30, 1946. The following day he noticed malaise, sore throat and anorexia. On Sept. 1, 1946 there developed severe headache, vomiting and some stiffness of the neck and back. The local physician performed a spinal puncture and found 660 cells per cubic millimeter.

On admission his temperature was 102.8 F., his pulse rate 96 and his respiratory rate 18. There was no bulbar or spinal involvement. However, the patient appeared mildly confused. On the second hospital day the patient appeared to have some difficulty in breathing and was placed in a respirator. He became decidedly apprehensive and restless. In spite of apparently adequate oxygenation he soon became completely disoriented. He slept only at short intervals and when awake was *often uncooperative*. He refused to take food and fluids and at *times talked* incoherently for long periods. He complained of diplopia. He appeared to be getting along fairly well when he suddenly became cyanotic and expired.

(b) Focal Encephalitic Group.—Clinical evidence of focal cerebral lesions has been reported on numerous occasions in the literature on poliomyelitis. In addition focal lesions which were clinically silent have been demonstrated pathologically. It seems probable that the focal signs are due to actual inflammatory involvement of the implicated structure. We observed a discrete inflammatory destruction of a considerable portion of the dentate nucleus in 1 patient.

Aphasic disorders have been reported rather infrequently. Nielsen and Von Hagen[16] reported 1 case of visual verbal agnosia due to poliomyelitis. Cerebral motor phenomena have been reported with greater frequency. These include myoclonic jerks as well as grand mal convulsions. In some instances the convulsions have been reported as persisting long after recovery from the acute phase of the disease. Spastic hemiparesis[17] has been reported not uncommonly in the literature. Hydrocephalus has been attributed to acute poliomyelitis.

Among the patients observed at the University Hospitals during the 1946 epidemic there were a few examples of focal encephalitic lesions. In 1 patient there developed ataxia of voluntary movements of the left arm and leg. Several had severe recurring convulsions. Focal complications did not appear frequently enough to warrant any opinion as to their prognostic import. One patient with repeated convulsions died of central respiratory failure.

4. COMBINED BULBAR-CERVICOTHORACIC CORD GROUP

The patients in this combined bulbar-cervicothoracic cord group in addition to their bulbar symptoms required treatment in a respirator because of severe damage to the cervical and thoracic cord, which produced failure of the diaphragm and intercostal muscles. In this combined clinical group there were a considerable number of patients. The prognostic importance of a combined lesion, particularly in adults, is emphasized by the fact that only 5 of these patients survived. In children this combined lesion was not nearly so critical. The most frequent findings at necropsy in this group, aside from lesions of the nervous system, were hemorrhagic pulmonary edema, atelectasis, bronchopneumonia, pulmonary abscess and, in 1, a massive pulmonary embolism.

[17] Poynton, F. J.: Case of Polioencephalitis Affecting the Midbrain, Showing Involvement of the Pyramidal and Extrapyramidal Systems, Proc. Roy. Soc. Med. 13:53, 1919-1920.

CASE 6.—W. H., a boy aged 14, was admitted to the pediatric service of the University Hospital on Aug. 9, 1946. He was acutely ill and complained of pain in the neck, extreme weakness, inability to swallow and a nasal voice. There was mucus in his throat in large amounts. His temperature was 103 F.

Examination revealed paresis of the soft palate and a right lower facial weakness. His neck and back were rigid, and the Kernig's sign was bilaterally positive. The knee jerks were absent, but ankle reflexes were normal. His blood pressure initially was 115 systolic and 60 diastolic; it continued to rise until August 12, when it was 180 systolic and 106 diastolic. On this day the patient appeared much worse. The temperature, which had fallen to normal, rose again to 102.6 F. There was evidence of diaphragmatic paralysis, and the boy appeared disoriented. The facial musculature was weak on the right side, with partial involvement on the left. The sternocleidomastoid muscles were decidedly involved bilaterally. This boy was intelligent and cooperative and was able by postural drainage and suction to handle the fluids in his throat. Although use of the respirator was seriously considered on several occasions, it never became necessary. The blood pressure gradually fell. By the seventh hospital day it was 150 systolic and 90 diastolic, and by the eleventh day it had returned to 110 systolic and 80 diastolic. He recovered comparatively rapidly. On his fifteenth hospital day he took 2,160 cc. of fluids orally without choking.

SUMMARY

1. Bulbar poliomyelitis is not a single clinical entity but can be divided into a number of clinical groups, depending on the region of the medulla which is involved by the pathologic process.

2. The most frequently recognized form of bulbar poliomyelitis consists of involvement of the nuclei of the cranial nerves. Only destruction of the tenth cranial nerve furnishes an immediate threat to the life of the patient by producing an obstruction to the airway and subsequent asphyxia.

3. When the autonomic centers within the medulla are injured in poliomyelitis, symptoms of respiratory or circulatory failure result, even in the absence of severe cranial neural, intercostal or diaphragmatic paralysis.

4. Clinical symptomatology indicative of cerebral involvement is common in bulbar poliomyelitis. These symptoms usually are caused by anoxia and clear up after adequate oxygen therapy.

The Chemical Mediation of Nerve Impulses.—The studies of Loewi, Dale, Cannon and others have firmly established the validity of the concept of the chemical mediation of nerve impulses. It is now generally accepted that the effects of the somatic and parasympathetic nervous systems are produced by the liberation at the nerve endings of acetylcholine. This substance is quickly destroyed by cholinesterase, an enzyme present in the blood and tissue fluids. The effects of postganglionic sympathetic nerve impulses are the result of the liberation at the nerve terminals of epinephrine. The clinical implications of these findings are emphasized by the fact that in at least one disease, namely myasthenia gravis, the primary dysfunction may be attributed to interference with the mechanism of acetylcholine activity.—Bloomfield, Sylvan: Relative Deficiency of Parasympathomimetic Activity in Aqueous of Eyes with Chronic Simple Glaucoma, *Arch. Ophth.*, May 1947.

PENICILLIN INHALATION THERAPY IN RESPIRATORY INFECTIONS

Therapeutic aerosols with oxygen flows may be administered for topical therapy of the respiratory tract or for rapid systemic effect through absorption from the tremendous inner surface area of the lung. It has been demonstrated in animals[1] and in man[2] that inhalational material may be uniformly distributed and penetrates the outermost air sacs of the lungs. It is thus possible to obtain high local concentrations with varying blood levels via the "pulmonary route."

Continuous aerosolization with oxygen of bronchodilator, vasoconstrictor and chemotherapeutic agents has been employed in patients with asthma, pulmonary emphysema, pneumonia, gas poisoning and other types of bronchopulmonary diseases.[3] The specific advantages of penicillin over the sulfonamide compounds suggested its superiority as an aerosol[4] in the treatment of serious disease of the respiratory tract.

The physiologic rationale of penicillin aerosol therapy has been well established. Bryson and his colleagues[4d] demonstrated that penicillin aerosol penetrated the lungs, diffused into the blood stream and was excreted into the urine. Barach and his associates[5] confirmed

these observations in a group of patients with bronchopulmonary disease and developed the proper equipment and technic for penicillin aerosol therapy. In their detailed investigation of the fate of aerosols in the lungs Mutch and his colleagues[6] demonstrated the efficacy of aerosol therapy. They suggested the use of penicillin aerosol for the management of purulent bronchitis and bronchiectasis and as a prophylactic against the secondary pyococcic infection in influenza. Knott and Clark[7] carried these studies further. They demonstrated effective bacteriostasis in closed chambers and suggested a technic for the control of air-borne infections. Other investigators[8] have employed penicillin with encouraging results in the management of pulmonary infections. In most cases effective therapeutic levels in the blood and good topical effects have been obtained.

The present report concerns itself with a summary of our findings in the use of penicillin aerosol in the treatment of 118 patients with bacterial pneumonia, infective bronchial asthma, bronchiectasis, purulent sinusitis, pulmonary abscess, infective laryngotracheobronchial edema and chronic pulmonary emphysema.

TREATMENT AND TECHNIC

The maintenance of a constant high level of penicillin in the blood is not essential in purely local pulmonary infections without bacteremia. Topical penicillin levels can best be attained by administering concentrated doses six times daily. In patients with toxemia or septicemia additional doses, administered intramuscularly five or six times daily, may help in producing blood levels sufficiently high to clear the blood stream of bacteria. Infections of the lung, occurring as they usually do in well vascularized soft tissues, generally respond to concentrations of penicillin which are completely ineffective in the relatively avascular hard tissues.

The patients with pneumococcic pneumonia were treated for three to seven days; those with bronchiectasis or pulmonary abscess for seven days prior to surgical treatment or for six weeks for purely medical therapy; those with infective bronchial asthma, from three days through three weeks; those with streptococcic or staphylococcic pneumonia complicated with formation of abscess, generally for a minimum of three or four weeks. The other patients were treated until there was no further evidence of infection and the penicillin-susceptible organisms were eradicated.

The sodium or calcium salt of penicillin was used. Generally 25,000 units of penicillin were dissolved in 1.0 cc. of isotonic solution of sodium chloride and given at three hour intervals for six to eight doses daily. The patients with pneumococcic pneumonia generally received 25,000 units at two hour intervals for six doses and then at three hour intervals thereafter. The patients with the more serious types of pneumonia and pulmonary abscesses received 50,000 units in 2.0 cc. of isotonic solution of sodium chloride. Those with acute or chronic sinusitis were treated with the 25,000 unit dosage. We found these patients able to take with complete tolerance 50,000 or even 100,000 units in 2.0 cc. of isotonic solution of sodium chloride via the nasal route.

In our earlier series[9] of cases we observed no systemic, toxic or allergic manifestations. However, more recently[10] we have observed local and generalized manifestations which consisted of edema of the lips or mucosa of the mouth and, in several instances, the development of a generalized urticaria. The local reactions generally cleared up after changing to another type of penicillin. The urticaria of 1 patient cleared up promptly when treatment ceased and did not return later when a different lot of penicillin was used. In a recent case with complicating urticaria we were able to continue with the same lot of penicillin by adding diphenhydramine hydrochloride ("benadryl hydrochloride" N. N. R.) orally. This new synthetic antihistamine agent apparently was of value.

The apparatus generally used in our studies was the basic "vaponefrin nebulizer" enlarged to a 2 liter size to permit the utilization of the expired penicillin. This nebulizer produced a fine voluminous mist or smoke screen with a particulate size of most of the molecules of less than 1 micron. A piece of rubber tubing connected the nebulizer with a regulator attached to an oxygen tank. Oxygen flows of 5 to 7 liters were generally sufficient to aerosolize 1.0 cc. of the penicillin solution in approximately fifteen minutes. To avoid loss of the drug in expiration, a glass Y tube, or simple opening, was placed just proximal to the inlet of the nebulizer. The patient or nurse was instructed to close the open end with one finger on inspiration and to remove the finger on expiration. With this technic the oxygen by-passed the nebulizer in the expiratory phase of respiration and no penicillin was lost through the carburetor opening of the nebulizer. Occasionally an Emerson demand valve system was attached. This had the advantage of automaticity and did not require the patient's cooperation with the Y tube. This was of particular value in the seriously ill patients.

For those patients unable to use the above technic the O. E. M. mask can be incorporated. The oxygen entrance tube may then be closed off. Infants and small children can best be treated in enclosed plastocele hoods or in specifically constructed closed chambers utilizing the basic nebulizer and oxygen flows as described.

The basic "vaponefrin nebulizer" can also be attached to the tracheotomy tube whenever topical penicillin aerosol therapy is desired in tracheotomy cases. We found this of particular value in 2 patients with acute laryngotracheobronchial edema characterized by pronounced cyanosis and inspiratory retraction. These patients were moribund at the outset of therapy. For these patients instead of using oxygen we have introduced a mixture of 75 per cent helium and 25 per cent oxygen directly through the nebulizer. One cubic centimeter of "vaponefrin inhalant" (a solution of synthetic racemic epinephrine hydrochloride) was aerosolized just preceding the penicillin aerosol for the relief of bronchospasm. This technic may prove to be of life-saving value in patients with laryngotracheobronchial obstructive disease.

LEVELS OF PENICILLIN IN THE BLOOD

Absorption of penicillin from the pulmonary tree into the blood stream was demonstrated by the effective levels of penicillin in the blood, which ranged from 0 015 to 0 225 unit per cubic centimeter in one hundred and eighteen determinations. Generally higher levels were obtained in those with extensive pulmonary involvement of a pyogenic type, that is, those with pneumonia or pulmonary abscess. Peak levels were observed at the end of one half hour, and in some cases they persisted for as long as two hours. Higher levels in the blood were obtained with the higher doses The absorption of penicillin into the blood stream is not necessarily a measure of the topical effectiveness of penicillin aerosol. The levels will vary according to the individual breathing pattern, equipment, dosage and type of penicillin, absorption variations of accumulated pus and secretions and, finally, the technic for the determination of the penicillin levels. In most of the cases the determination of levels in the blood is more of academic interest than of practical value. The clinical course is sufficient proof of the topical effectiveness of penicillin aerosol and is best demonstrated in the patients with pneumonia and pulmonary abscess.

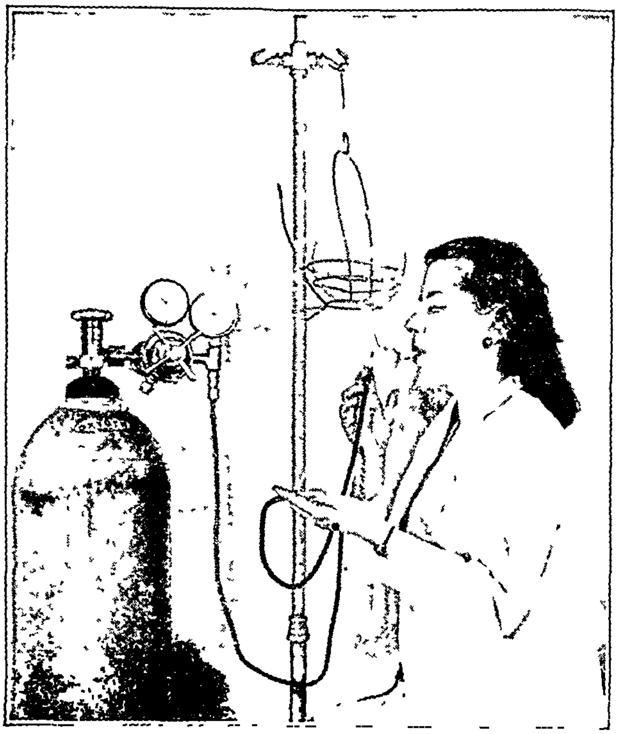

Fig 1 —Penicillin aerosol apparatus suspended from a clysis stand The "Vaponefrin" nebulizer (Vaponefrin Company) with a 2 liter rebreathing glass bulb, Y tube for controlling the flow of oxygen only and rubber tube connection to the oxygen regulator

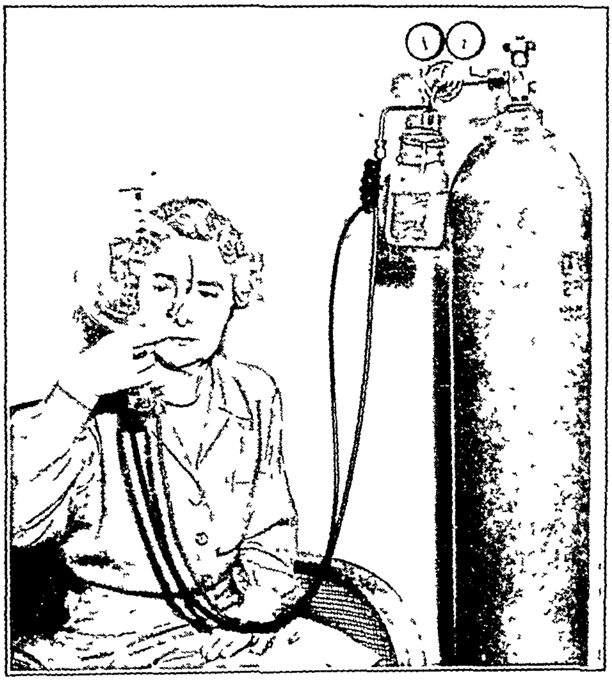

Fig 2 —Penicillin aerosol rebreathing apparatus with humidifier and Emerson demand valve (J. H. Emerson Company) to supply aerosol on inspiration only The apparatus is most suitable for the sickest patients

We[10] compared the levels of penicillin in the blood in a series of normal subjects[21] receiving 50,000 units of penicillin-saline aerosol and, at a later time, 50,000 units of penicillin and 1 per cent "neo-synephrine" aerosol. The average curve obtained with the penicillin and "neo-synephrine" aerosol appeared slightly lower than the one obtained with penicillin-saline aerosol, particularly at one half and at one hour. This may be interpreted as indicating that "neo-synephrine" delays the absorption of penicillin through the pulmonary tree. We are carrying these studies further. A therapeutic agent which could achieve greater topical efficacy and less systemic effect would prove of considerable value in combating chronic pulmonary disease.

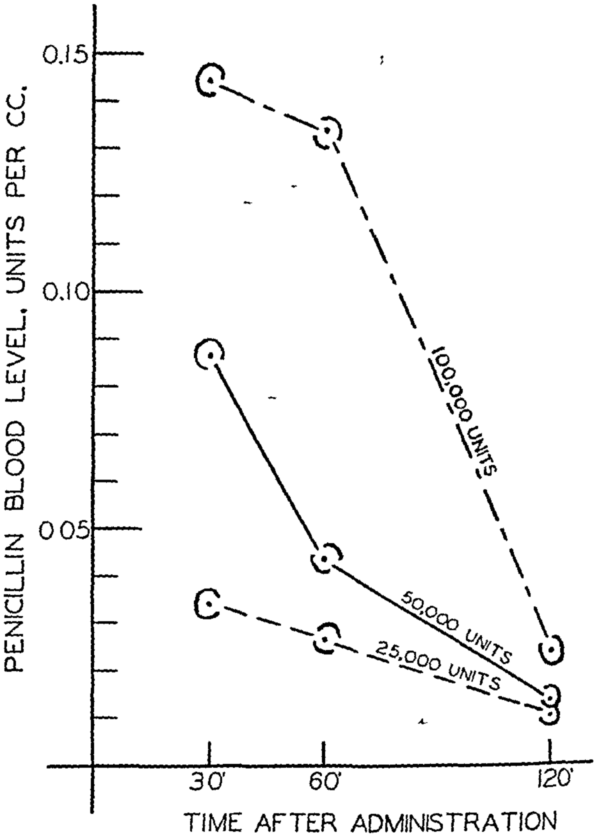

Fig 3 —Levels of penicillin in the blood after administration of penicillin aerosol; thirty seven trials

PNEUMONIA

Observations in this group definitely proved the topical bacterial effectiveness of penicillin aerosol on the organisms in the bronchial mucosa and alveoli and can serve as the pharmacologic rationale for its subsequent use in suppurative pulmonary disease. We believe that these are the first cases of bacterial pneumonia in which treatment was with penicillin aerosol.

---

[21] This work was aided by a grant from Frederick Stearns & Company.

Wilson and his colleagues[11] recently demonstrated the effectiveness of penicillin aerosol in experimental type I pneumococcic pneumonia in rats. Somewhat better results were obtained from inhalation than from intramuscular injections of the smaller dose of penicillin (250 units per dose), while with the larger dose (500 units per dose) there was no difference in the percentage of survivals.

We obtained clinical cures in 11 patients with pneumococcic pneumonia and in 1 patient with an acute pulmonary infarct and pneumonitis. The response was striking. Their clinical charts returned to normal promptly, they felt fine throughout treatment, and no complications were encountered. The sputum became negative on the second or third day and remained so at time of discharge six to ten days after hospitalization. The case histories of the first 6 patients appear on figure 4.

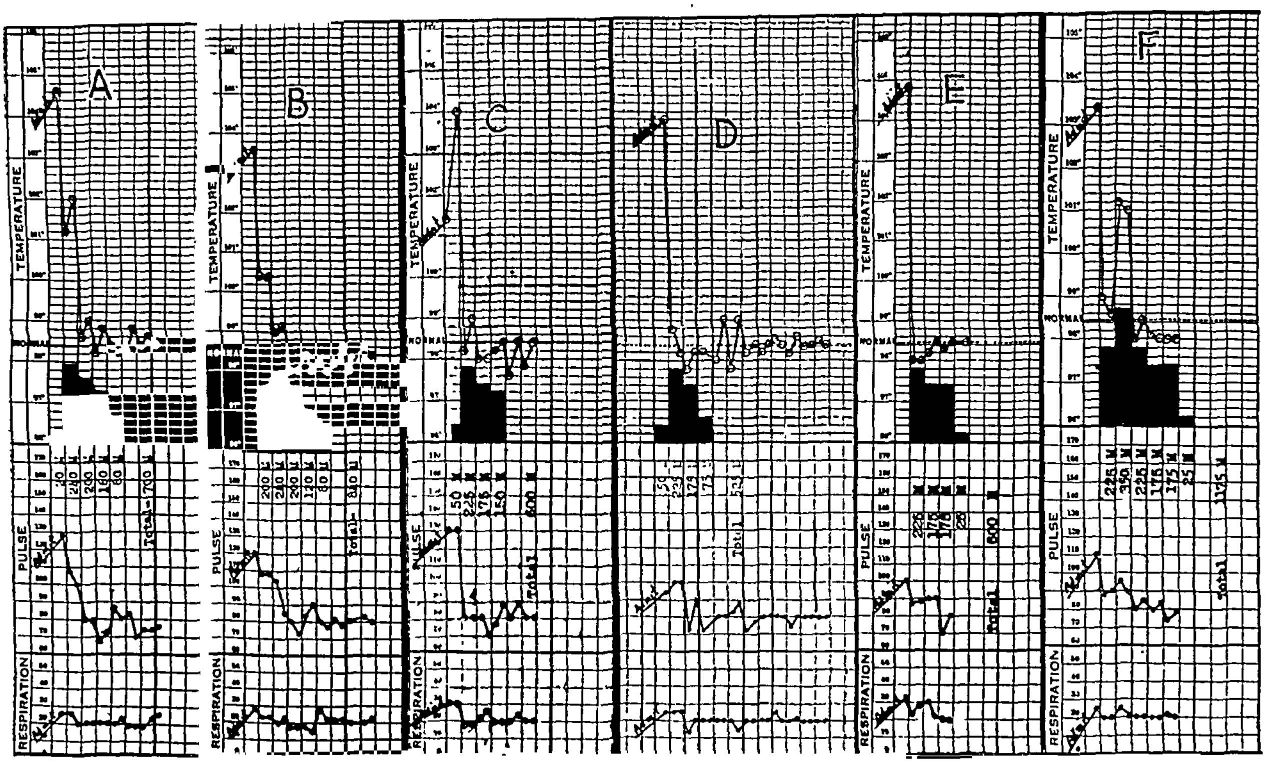

Fig. 4.—Patient A was a 34 year old woman with type 4 pneumococcic pneumonia of the lower lobe of the left lung. Patient B was a 26 year old woman with type 12 pneumonia of the lower lobe of the left lung. Patient C was a 16 year old girl suffering from type 33 pneumonia of the lower lobe of the left lung. Patient D was a 68 year old woman with pulmonary infarct and acute pneumonitis. Patient E was a 24 year old woman suffering from type 1 pneumococcic involvement of the lower lobe of the left lung. Patient F was a 39 year old man suffering from type 1 pneumococcic pneumonia in both the lower lobe of the left and the upper lobe of the right lung.

We do not advocate penicillin aerosol for the routine therapy of patients with pneumococcic pneumonia. The simpler procedures employing the sulfonamide compounds or penicillin are preferable. However, for the management of streptococcic and staphylococcic pneumonia and pneumonia due to penicillin-susceptible strains of Friedländer's bacillus, we are of the opinion that penicillin aerosol therapy is more effective than parenteral therapy alone. Combined aerosol and intramuscular therapy may be employed in patients who are seriously ill, particularly patients with septicemia.

Fullerton and Shane[12] recently reported their observations with penicillin aerosol in 14 patients with bronchopulmonary disease. They confirmed our previous observations[13] and reported dramatic improvement in 3 patients with pneumococcic pneumonia.

For patients with staphylococcic pneumonia the therapy should be continued for at least one week after all the clinical and roentgenographic signs of infection have subsided. As these lesions tend to become fibrosed and walled off, protracted therapy is advisable to insure complete eradication and to prevent exacerbations and formation of abscesses.

In order to control pneumonia due to penicillin-susceptible strains of Friedländer's bacillus we have employed massive doses of 100,000 units at three hour intervals in 2 such patients. In 1 of these patients a blood level of 0.250 unit of penicillin per cubic centimeter was obtained one half hour after the inhalation of 100,000 units. In both these patients the organisms rapidly disappeared and remained absent during the course of therapy. In 1 of these patients, however, the organisms recurred, although the patient remained symptom free for some time after discontinuance of therapy.

It appears from the literature that streptomycin may prove of value in infections of the lungs with Friedländer bacillus, Hemophilus influenzae and tubercle bacilli. The combined intramuscular and aerosol routes may prove most efficacious in such cases. Durant and his colleagues[14] reported on the remarkable effectiveness of streptomycin therapy in 3 patients with type B H. influenzae pulmonary infections. The intrabronchial route of administration alone was effective in 2 cases with chronic suppurative disease. In a third case, of extremely acute bilateral suppurative pneumonitis, the combined intramuscular and intrabronchial routes were used most effectively. A recent case report from the Mayo Clinic[15] described a rather remarkable cure of isolated laryngeal tuberculosis with parenteral and aerosol administration of streptomycin. Our own experience has been limited to 2 patients with bronchiectasis due to gram-negative Friedländer organisms in whom streptomycin-resistive strains rapidly appeared which could not be eradicated despite tremendous doses. We have not observed the appearance of penicillin-resistive strains in our cases in which penicillin aerosol was used. The evidence so far available suggests that except for staphylococcic infections penicillin resistance will probably not be of any great clinical importance. The possible appearance of streptomycin-resistive strains with aerosol therapy should be taken into consideration before instituting such therapy. Unfortunately, streptomycin also has toxic potentialities which may possibly be attributed to the impurities now present in many commercial preparations. Serious and fatal histamine-like reactions and damage to the eighth nerve in human beings, and delayed fatty infiltration of the kidneys in animals, have been observed. These difficulties will no doubt become minimized with more careful control of the production of streptomycin.

The case histories[16] and clinical charts of the first 6 patients with pneumonia treated with penicillin-aerosol appear on figure 4.

INFECTIVE BRONCHIAL ASTHMA

A course of penicillin aerosol lasting from three days to three weeks was given to 22 patients with severe chronic infective bronchial asthma. The penicillin-susceptible organisms promptly disappeared and in most cases remained absent during hospitalization. We found such therapy generally disappointing in these patients, although striking improvement was occasionally observed. In these patients the proper control of the primary bronchial infection with intramuscular administration of penicillin and oral administration of sulfonamide drugs has proved equally disappointing. Engelsher[8f] recently commented briefly on his observations in 74 cases of bronchial asthma, stating that he found it of questionable value in a small percentage and of no value in the majority of cases of bacterial asthma. Most of our patients observed, however, that they were able to raise sputum more easily while getting the penicillin aerosol. Many objected to the taste and irritating qualities of the aerosol. The danger of local or generalized allergic reaction to penicillin aerosol in the asthmatic group must always be kept in mind. Most of the local and urticarial reactions which we have observed have been in patients with bronchial asthma or bronchiectasis. We have recently observed the onset of mild bronchial asthma in 2 patients receiving penicillin aerosol therapy for the management of chronic bronchitis and emphysema and in 2 patients with bronchiectasis. The patients were free of asthma before these attacks. The attacks subsided promptly when inhalations of epinephrine were given after the penicillin aerosol had been discontinued.

One of our most striking remissions was observed in a patient with chronic intractable bronchial asthma who was treated in the Barach rebreathing hood apparatus with mixtures of 75 per cent helium and 25 per cent oxygen under positive pressure. In addition the penicillin aerosol was introduced directly into the hood apparatus. Marked clinical improvement occurred after several days of such therapy. However, it was rather difficult to evaluate the specificity of penicillin aerosol therapy in this particular case, for we have made similar observations in many patients who were being treated with helium and oxygen under positive pressure without penicillin aerosol.[3c, d]

BRONCHIECTASIS

A series of 42 patients with chronic bronchiectasis were treated with penicillin aerosol. Eight of the patients had subsequent surgical treatment. Most of the patients received an initial course of therapy of at least six weeks and subsequently returned for an additional seven days of therapy at three to six month intervals. Postural drainage was carried out just prior to each treatment. Several of these patients continued to take penicillin aerosol therapy once daily at home throughout this period of time. We have found this procedure most effective in preparing the patient for operation and in preventing postoperative infections. Defervescence, lessening of toxicity, diminution in the amount of daily sputum, loss of its foul character, rapid disappearance of the penicillin-susceptible organisms, improvement in the patient's appetite and gain in weight were uniformly observed. Considerable improvement was observed in the bronchograms of several patients with involvement of a single lobe. This therapy was most helpful in the control and prevention of pneumonitis, which recurs in many patients with bronchiectasis. It was also of value in those patients who were considered to be unsuitable for lobectomy or pneumonectomy or who refused to undergo such procedures.

We are ever mindful that the anatomic changes accompanying bronchiectasis are generally permanent ones and cannot be changed by any type of therapy save resection. These patients are subject to repeated episodes of infection, pneumonitis or involvement of other lobes. The mucosal secretions in bronchiectasis largely result from the structural changes in the endothelial lining of the small bronchioles. Invasive organisms contribute by further destruction of the bronchioles. Infection can be eradicated or eliminated by penicillin aerosol. We are in full agreement with Olsen[8a, b] that it thus becomes the ideal therapy for preoperative and postoperative cases.

Many of our patients had previously received courses of penicillin administered intramuscularly and sulfonamide drugs given orally without the striking effects obtained from penicillin aerosol therapy. The vital capacities of most of these patients increased from 30 to 40 per cent above the levels before aerosol therapy and have remained fairly constant at the improved figure. Penicillin aerosol therapy can easily be carried out in the patient's home under supervision.

[16] These histories were previously published in full.[4b]

The penicillin-susceptible organisms uniformly disappeared from the sputum under such therapy. Frequently we observed the appearance of gram-negative organisms which were refractive to penicillin aerosol therapy. A recent report by Olsen[8b] demonstrated the value of streptomycin aerosol in 9 patients with whom penicillin aerosol therapy had failed. He employed doses of 500,000 units in 20 cc. of isotonic solution of sodium chloride per day by nebulization. The streptomycin-susceptible organisms were uniformly eradicated and a reduction in the volume of sputum followed immediately. Our experience with streptomycin aerosol has been limited to 2 patients with gram-negative Friedländer organisms. In our first trial with this drug the streptomycin-susceptible organisms rapidly disappeared when 100,000 units at three hour intervals were employed, but returned after several days of therapy. We then found it necessary to increase the dose. After a while the organisms became more resistive and could not be eradicated despite tremendous doses. The possible appearance of streptomycin-resistive strains with aerosol therapy should be taken into consideration before instituting such therapy. Also the practical usefulness of the drug may be limited by its possible toxicity, the appearance of resistive strains and its cost.

SINUSITIS[17]

In evaluating a preliminary report such as this clinical study of penicillin aerosol in the treatment of sinusitis one must be careful to diagnose whether the sinusitis be acute, subacute or chronic. Of the 18 cases thoroughly studied clinically and by roentgen rays there were 9 cases of chronic sinusitis complicated by bronchiectasis, 5 cases of chronic sinusitis uncomplicated by pulmonary disease and 4 cases of acute sinusitis. Most of the patients classified as having chronic sinusitis with bronchiectasis had previously had radical sinus operations and subsequent reinfection. The patients with acute sinusitis had previously had local therapy, including penicillin administered intramuscularly, without much satisfactory progress.

After an examination of the nasal passages of a patient having sinusitis with edema of the nasal mucosa it is not difficult to realize the problem of getting any substance, whether in the form of a fluid or a mist, through the edematous ostiums and into the respective sinuses despite shrinkage of the passages with vasoconstrictor drugs. Theoretically one must be reminded of the obstacle offered by the turbinates as baffle plates in disturbing the inflow of the penicillin aerosol. The presence of secretions in the nose also acts as an obstacle in preventing absorption and utilization of the penicillin aerosol.

At the onset of the study it was felt that if penicillin could be brought to all the sinuses in greater concentration and kept there for longer periods of time a more beneficial result could be obtained. Studies were therefore undertaken to determine whether penicillin actually found its way into the sinuses by way of the ostiums or whether it was brought to the sinuses through other channels. Certain radiopaque aqueous substances such as "skiodan" N. N. R. and "diodrast" N. N. R., ranging in concentration from 10 per cent to 60 per cent, were aerosolized into the nasal passages. Immediate follow-up roentgenograms showed that radiopaque material had not found its way into the sinuses. This experiment, simple as it was, seems to imply that penicillin gets into the sinuses by way of the veins and lymphatics from the mucosal lining of the nose rather than by way of the ostiums.

The procedure followed in the treatment and study of the patients included follow-up cultures of the nose, throat and sputum and roentgenograms of the sinuses and chest before and at the conclusion of the treatment. In the early days of the study 16,000 units of penicillin in 2.0 cc. of isotonic solution of sodium chloride were given every three hours except at 3 a. m. Later this was increased to 25,000 units every three hours. "Neo-synephrine hydrochloride" N. N. R., 0.25 per cent, was utilized as the shrinking agent before treatment in most cases. If pulmonary disease was present the nasal inhalations preceded the oral inhalations.

Two case histories follow:

Case 1.—The patient, aged 19, had been given a diagnosis of bilateral chronic pansinusitis with subacute exacerbation. Since the age of 4 she had had almost no sense of smell. She had had frequent exacerbations with innumerable local treatments. Prior to her admission to the hospital the patient had had a fresh exacerbation which persisted for weeks despite local treatments and instillation of penicillin directly into the nose after shrinking and suction. Cultures taken from the nose and throat before treatment showed hemolytic streptococcus, group A, and coagulase-positive hemolytic Staphylococcus aureus. After four days of penicillin aerosol therapy only, preceded by nasal shrinkage and with one daily postnasal wash, the thick purulent nasal discharge became mucoid and disappeared completely on the fifth day. For the first time in years her sense of smell returned. A subsequent check-up revealed no purulent secretions in the nose and pronounced subjective and objective improvement. A culture taken one week after the beginning of the treatment showed the absence of the originally noted virulent organisms.

Summary of Cases of Bronchiectasis

42	Total treated
8	Subsequent operation—no postoperative complications
14	Considered unsuitable for operation—multiple lobe involvement—temporary clinical improvement in hospital—diminution in amount of sputum and in cough—recurrence in most of these cases within one to six months
20	Purely medically managed; involvement of one or two lobes, mostly lingula; marked clinical improvement in 14 cases and remission for as long as a year and a half in 2 cases; no recurrence of pneumonitis in 6 cases under observation for as long as nine months; failure to get a lasting remission in 6 cases for longer than three to five months; repeated courses of therapy necessary in this group
Reactions	Two patients had their first attacks of bronchial asthma; 2 patients had severe generalized urticaria; 4 patients had temporary stomatitis and sore tongue

PULMONARY ABSCESS

We have employed penicillin aerosol therapy in a series of 11 patients with pulmonary abscesses. Seven patients with the aerobic nonodoriferous, postpneumonic type of pulmonary abscess recovered completely. Two patients with the anaerobic, putrid type failed to respond and subsequently recovered with surgical drainage. A third patient with a fulminating putrid pulmonary abscess failed to respond to penicillin aerosol therapy and died shortly after surgical intervention. One patient with a chronic putrid pulmonary abscess was prepared for lobectomy by penicillin aerosol and made an uneventful postoperative recovery. Our observations have impressed us with its value in the aerobic, nonodoriferous, postpneumonic type of pulmonary abscess. Results with the anaerobic, putrid, atelectatic types were disappointing. Doses of 50,000 units of penicillin given at three hour intervals were usually adequate. Postural drainage was generally carried out prior to each treatment. In the cases of more toxic and putrid disease we employed simultaneously 25,000 units of penicillin intramuscularly. Therapy was continued for at least four weeks. With an effective program of penicillin aerosol therapy it is possible to avoid operation in most of these cases. The occasional intrabronchial instillation of penicillin or streptomycin, depending on the organisms cultured, may also be of tremendous aid in aborting surgical treatment. In most of our cases cure was further confirmed by bronchograms by means of iodized poppy-seed oil 40 per cent. Treatment was employed for a minimum of four weeks and for a maximum of ten weeks. A report of 1 of our cases follows. Detailed case histories may be found in our earlier papers.[13]

---

[17] This work was carried on at the Massachusetts Eye and Ear Infirmary.

One typical patient presented a clinical picture of extreme toxicity associated with a postpneumonic pulmonary abscess. The odor of his sputum was extremely foul. A course of penicillin aerosol for five weeks produced a clinical cure. A bronchogram by means of iodized poppy-seed oil 40 per cent then revealed a small residual cavity, presumably in the lingula. An additional ten days' course of therapy completed the cure.

ACUTE LARYNGOTRACHEOBRONCHIAL EDEMA

Six patients with acute laryngotracheobronchial edema associated with serious infection were treated with penicillin aerosol. The first 3 patients were moribund at the outset of therapy. The conventional methods of employing sulfonamide drugs, penicillin given parenterally and oxygen therapy by catheter, mask and tent had been tried with little benefit. Dramatic improvement was observed as soon as the inhalation program was instituted. Mixtures of 75 per cent helium and 25 per cent oxygen were employed in these patients because of the evidence of localized inflammatory narrowing of the upper part of the laryngotracheal tree. It was the opinion of the many observers that the recovery of these 3 patients could be directly attributed to the therapy described. The other 3 patients were treated with oxygen flow and responded remarkably well. We have observed the most spectacular results in this group of patients.

A brief abstract of 2 cases follows:

Case 1.—A 46 year old man entered the hospital because of sore throat, high temperature and difficulty in breathing of twenty-four hours' duration. Previously he had contracted acute sore throat which was treated with irrigations and high doses of sulfonamide drugs. Just prior to admission the family physician found him struggling for breath. There was pronounced edema of the hypopharynx. In the hospital an emergency tracheotomy was performed. During this procedure he aspirated much blood and massive atelectasis and pneumonia developed. He appeared moribund and cyanotic. Despite suction, oxygen and high doses of penicillin intramuscularly, marked inspiratory stridor, severe cyanosis and anoxia developed and the temperature rose to 105 F. About sixteen hours after hospitalization a program of therapy was instituted consisting of the following: A flow of 75 per cent helium and 25 per cent oxygen was directed through the "vaponefrin nebulizer" which was attached directly to the tracheotomy opening in this fashion. Intermittent suction was carried out at periodic intervals just prior to such therapy. The change was striking almost as soon as this therapy was instituted. The stridor became less pronounced and the patient more rational and cooperative. This treatment was continued for several days; the temperature promptly returned to normal and the signs of atelectasis and consolidation of the base of the right lung improved by clinical and roentgenographic observations. The patient made an entirely uneventful recovery.

PULMONARY EMPHYSEMA AND EMPHYSEMATOUS BLEBS

Patients with chronic pulmonary emphysema generally present a history of cough, progressive dyspnea even at rest, loss of weight and weakness. The lung has lost its "pre-war rubber," and in its place a "synthetic quality" has developed. Many have severe clubbing of the fingers and cyanosis, and a small number have severe emphysematous blebs. Bronchiectasis and evidence of bronchospasm may also be found in many of these patients. They are subject to recurrent bouts of infections of the respiratory tract and their pulmonary reserve diminishes with each bout. The prognosis is generally poor, and progressive respiratory failure ensues. The patients can be made more comfortable with the use of 50 per cent concentrations of oxygen, theophylline ethylenediamine and aerosolized bronchodilator drugs. Supplemental elevation of the diaphragms by manual manipulation in expiration[19] and the use of a proper abdominal belt may be of considerable value. Oral administration of sulfonamide drugs has proved of little value in our patients for the prevention of recurrent infection.

Recently we have observed striking improvement in a series of 7 patients with severe pulmonary emphysema when penicillin aerosol was added to the program described. In one of these patients diffuse emphysematous blebs and a minimal basal bronchiectasis complicated the picture. In another patient a giant acquired cyst occupied the entire upper lobe of the right lung. Five patients had uncomplicated pulmonary emphysema secondary to recurrent bronchial infections. These patients were considerably improved after a course of penicillin aerosol therapy of from one to six weeks. They had been treated with oxygen and bronchodilator drugs first, but despite this more progressive dyspnea, cyanosis and cough developed. After administration of penicillin aerosol their vital capacities improved slightly, and they have been able to maintain this improvement at home while continuing the previously outlined therapy. These remissions have been striking although probably temporary.

CONCLUSIONS

Penicillin aerosol therapy is of definite value in the management of bronchopulmonary disease. It can be carried out best with the simple rebreathing technic described. This may be modified according to the age of the patient and the nature of the illness. For patients manifesting obstructive disease of the respiratory tract streams of helium and oxygen may be developed in the place of oxygen. The penicillin aerosol may also be directed into tents, masks and tracheotomy openings. If indicated, other chemotherapeutic, antibiotic and chemical drugs may be substituted for penicillin. Finally, the penicillin aerosol may be directed nasally for the management of patients with acute and chronic purulent sinus disease, preferably with the technic of intermittent negative pressure and replacement with penicillin aerosol.[16b]

Penicillin aerosol therapy should not be employed by the nasal or pulmonary route for the management of the common cold. This infection generally runs a self-limited course despite all useful therapy, and one must always bear in mind the possible appearance of penicillin-resistive strains after repeated or prolonged use of penicillin aerosol therapy.

---

[19] Barach, A. L.: Inhalation Treatment of Bronchial Asthma, New York State J. Med. 46: 1002-1008, 194

Penicillin aerosol therapy should be reserved for patients having the following conditions: purulent sinusitis, bronchiectasis, pulmonary abscess, infections of the lungs with streptococcic or staphylococcic organisms or with penicillin-susceptible strains of Friedländer's bacillus, acute laryngotracheobronchial edema and infections secondary to underlying primary disease of the lungs, such as pulmonary emphysema, pulmonary cysts and infarcts. Before instituting therapy every attempt should be made to identify the organisms of the nose, throat and sputum.

ABSTRACT OF DISCUSSION

Dr. William J. Kerr, San Francisco: We have known for some time that bronchiectasis and some other pulmonary diseases outside of pneumonia will respond favorably to the use of intramuscular or intravenous administration of penicillin and other antibiotics. We now have good evidence, I think, that penicillin is useful in this manner. One must, however, deplore the promiscuous use of penicillin by the oral route or by the use of aerosols. Almost everywhere it is being used for all sorts of nasopharyngeal disturbances or nasal disturbances in the respiratory tract, many of which are not on an infectious basis at all. I for one could not believe that a common cold is an infectious disease, although that is a matter of definition, perhaps, and subject to argument on some other points. One thing which has interested me about the use of penicillin as an aerosol is that one of the patients that we had who was using this method suffered from fungous infection, Monilia albicans infection involving the lungs and possibly other parts of the body. He had been given penicillin intramuscularly without any serious trouble about two monhts before, and when we tried the aerosol method, almost immediately this young man had a most remarkable attack resembling bronchial asthma; we thought that he was going to die. Fortunately, he recovered from this, and we have not tried it again, but cutaneous tests show remarkable reactions—positive reactions with infinitely small doses of penicillin. Another patient was a man interested in the manufacture of penicillin, and he had much of it available. A few months ago he took some lozenges of penicillin for a sore throat, with good response. About two months later, another sore throat developed, and he took by mouth a large single dose of about 1,000,000 units; the mucous membranes of his nasopharynx and the inside of his mouth, excepting the tongue, then began to burn terrifically. He had remarkable symptoms, and within a few hours he had sloughing of the tissues of the soft palate and in the nasopharynx. It was several weeks before he recovered from this episode. The question arises whether it was sensitivity to the drug taken orally or whether something else had happened which I believe may be of importance in this general field. Many of us are interested in the balance of nature in relation to plant and animal life. The ecologic factors in the body of man and his organisms must be kept in mind. There is fairly good evidence now that if we use some of the antibiotics we can eliminate some of the organisms that live a more or less balanced existence with other organisms in the respiratory tract or the genitourinary tract or the gastrointestinal tract. It is possible that if we eliminate the streptococci, some of the other cocci and Monilia which may be in the mouth in a suppressed state will multiply in great numbers and cause some of the reactions which we have seen. Already there are patients subject to certain diseases which have, after long treatment with penicillin, developed other complications, and these may be on the basis of fungous infection or other infections arising from organisms which ordinarily are in balance or are suppressed. Here may be something of great biologic importance that we must not overlook in the use of the antibiotics.

Dr. Alvan L. Barach, New York: This interesting paper demonstrates that inhalation of penicillin as an aerosol has therapeutic effectiveness in cases of advanced bronchiectasis, pulmonary abscess and acute lobar pneumonia. It is our purpose, in presenting a relatively new technic, to determine whether this method of administration is required, whether it does anything that intramuscular or oral administration of penicillin will not do. The advantage of topical application of penicillin is illustrated in empyema, in which systemic administration is without value, whereas 30,000 units instilled in the pleural cavity every other day results in cure in the majority of early cases. In some cases of pulmonary abscess observed by Dr. Segal and in our clinic, penicillin aerosol has resulted in cure when previous intramuscular injection of the drug was ineffective. The pathologic situation in certain cases of pulmonary abscess and bronchiectasis may be characterized by the growth of bacteria on a purulent or fibrinopurulent exudate that is not reached by the capillary blood supply. The deposition of penicillin droplets on the bronchoalveolar surface may then result in a local concentration of the drug as well as an effective level in the blood. For prolonged treatment, inhalation of penicillin is also more feasible than either oral or intramuscular administration. Inhalation of penicillin aerosol does result in the disappearance of gram-positive organisms from sputum cultures and the finding of gram-negative bacteria, which we have observed in the majority of approximately 200 cases of bronchopulmonary disease. However, these gram-negative bacteria may disappear spontaneously later or, if their pathogenicity is established, may be treated by other antibiotics. About 15 per cent of treated cases manifest either a red tongue or a black tongue, and in perhaps 20 per cent of the allergic group urticaria develops. These reactions can be handled in various ways. The main objective in the use of penicillin aerosol is to offer the patient not only an effective method but one that he can use over long periods of time. Our penicillin levels in the blood, after inhalation of 50,000 units, which at first were 0.02 unit per cubic centimeter, are now 0.1 to 0.2 unit per cubic centimeter with the same dose. I think that no technic of administration of penicillin aerosol is desired which does not give an effective blood level. In our early use of sulfonamide aerosols we wanted a low blood level and a high topical concentration because of the hazards of long-continued high levels of sulfonamide drugs in the blood; with penicillin we have no such cause for alarm. A reasonably effective level in the blood is an added gain along with topical application of the drug. I think that the series of cases presented by Dr. Segal provides additional justification for the trial of this relatively new technic.

Dr. Arthur M. Olsen, Rochester, Minn.: Dr. Segal has demonstrated that penicillin aerosols have a wide range of usefulness in the treatment of serious respiratory disease. For various reasons, my reports on inhalation therapy have been restricted to its use for chronic suppurative bronchiectasis. However, at the Mayo Clinic we have had a limited experience with nebulization therapy in certain other respiratory conditions. For several years we have used nebulizers to moisten the oxygen given after tracheotomy to children who have acute laryngotracheobronchitis. Distilled water or isotonic solution of sodium chloride alone or in combination with propylene glycol have been nebulized by a stream of oxygen which passes through the nebulizer into the tracheotomy tube. The prognosis of this condition has been significantly altered as a result of this treatment. No longer does the bronchoscopist have to maintain a constant vigil to remove the dry crusts which constantly threaten to block the trachea or bronchi. Recently weak solutions of penicillin in isotonic solution of sodium chloride have been employed, and the results have been encouraging. In the treatment of bronchial asthma our results with the use of penicillin aerosol are similar to those reported by Dr. Segal. The aerosol helps to thin out tenacious secretions, and in some instances the volume of sputum has been reduced. However, the results have been temporary and disappointing in our cases of asthma. Four patients who had chronic pulmonary abscess have been treated at the Mayo Clinic with aerosols of antibiotic preparations. Two of these patients who had single pulmonary abscesses of several months' duration were treated with combined penicillin and streptomycin aerosols for four weeks. Both patients were greatly improved, and complete relief of fever, cough and expectoration was obtained. Roentgen examination revealed complete clearing of the lesion in one case and considerable improvement in the other case. The other 2 patients did not respond to aerosol therapy. A fifth patient who had an acute postoperative pulmonary abscess improved after treatment with penicillin aerosol. In my experience patients who had emphysema have not been greatly benefited by aerosol therapy. Poor mixing of tidal and residual air appears to account for the poor results obtained. Perhaps the patients whom we treated were too breathless to inhale the penicillin aerosol efficiently. The concentration of penicillin in the blood has been negligible in these cases, and little penicillin has been excreted in the urine. For those patients who had limited respiratory reserve associated with bronchiectasis, the supraglottic instillation of aerosols has been used to good advantage. We have had little experience with the aerosol in the treatment of sinusitis. However, after successful aerosol treatment of bronchiectasis it is remarkable how much improvement has been observed in the condition of the sinuses. As yet we have not used aerosols in the treatment of acute pneumonias. The development of bacterial resistance to antibiotic preparations has been emphasized by Dr. Segal. In my experience resistant bacteria are likely to appear in pulmonary secretions after treatment with both penicillin and streptomycin. I agree that streptomycin-resistant, gram-negative bacteria are encountered more frequently than gram-positive bacteria which are not sensitive to penicillin. The average daily output of sputum of one of our patients who had bronchiectasis in all five lobes was 800 cc. when he entered the hospital. Hemolytic streptococci were abundant. After four weeks of treatment with penicillin aerosol his daily output of sputum was reduced to 200 cc. Gram-negative bacteria then were demonstrated which were sensitive to streptomycin by in vitro tests. After continued treatment for two more weeks with streptomycin and penicillin aerosols, the output of sputum was reduced to 100 cc. daily and has remained constant. The sputum contained a strain of Escherichia coli in large numbers. Growth of these bacteria was not inhibited in vitro by 200 units of streptomycin per cubic centimeter of culture medium. I agree with Dr. Segal that aerosol therapy with antibacterial agents has a real place in the treatment of respiratory infections caused by bacterial organisms. It seems unlikely that the method will be helpful in combating acute infections of the upper respiratory tract of virus origin. In the further evaluation of this method of therapy I should like to emphasize the necessity of careful bacteriologic studies.

Dr. Maurice S. Segal, Boston: With reference to Dr. Kerr's comments, we too have repeatedly stressed that one should not promiscuously use penicillin aerosol therapy. It has a distinctly limited place and its use should be restricted to those indications which we all have stressed from time to time. We have observed reactions; the onset of bronchospasm, 2 cases of urticaria, and 4 cases of serious stomatitis. In most instances, by changing to another type of penicillin or, as in 2 striking cases, by adding "benadryl," we were able to continue with penicillin aerosol therapy. Dr. Barach has stressed an excellent point: namely, that some of his patients had received parenteral penicillin therapy and sulfonamide drugs with failure prior to receiving the penicillin aerosol therapy. Such was our experience, particularly in pulmonary abscess, staphylococcic pneumonia and several cases of bronchiectasis. Two of our patients with penicillin-susceptible strains of Friedländer organisms had received large amounts of penicillin parenterally without success, but when penicillin aerosol therapy was used, the results were striking, indeed. The question of levels in the blood, I think, will depend a lot on the type of apparatus used, the breathing pattern, the tidal air exchanged, the amount of suppurative disease and the vascularity of the lung. In most instances an effective level in the blood can be obtained with 50,000 and 100,000 unit doses. Our minds should be receptive, albeit critical, regarding the future of all types of aerosol therapy. We may be entering a new era of pulmonary route therapy in place of, or supplementing, the more usual routes. The value of such therapy can be appreciated if one recalls that the inner surface of the lung has an area five hundred times as great as the surface of the body and absorbs so rapidly as to give an effect similar to that of an intravenous injection.

SPERMATOGENESIS AND THE THERAPY OF INFERTILITY

EDWARD T. TYLER, M.D.
and
SHELDON PAYNE, M.D.
Los Angeles

In recent years the problem of infertility has been undergoing a decided change. Formerly looked on by many physicians as essentially a woman's problem, with little responsibility attached to the husband, it is now considered one in which the husband is probably at fault nearly as often as the wife. Many investigators in the past few years have placed the husband's responsibility in infertile matings at figures that range from 30 to 50 per cent, and even higher. For example, Keshin and Pinck[1] found in a series of 135 cases that defective semen was a factor in 68 per cent. Meaker and Vose[2] reported that the responsibility for infertility was divided between husband and wife in 78 of 100 cases. Lane-Roberts[3] quoted results in study of a series of 26 women who attended an outpatient sterility clinic, in which the semen of the husband showed impaired fertility in 19 instances.

Analysis of Sixty-Five Couples Previously Treated by Physicians for Two to Sixteen Years and Referred Primarily as Gynecologic Problems

Trouble Found Primarily	No. of Cases
Female	21
Male	17
Both male and female	27
Total	65

Male factor important in 44 cases

In a problem like infertility, in which there are so many etiologic considerations, it is often impossible to assign definite responsibility to any one factor in either the husband or the wife. Many times the cause is a combination of several factors which, in the average couple seeking help, combine to make pregnancy impossible. It is generally considered that the fertility of a union is a combination of the individual fertility of each partner and that when the summation of the two falls below a theoretic threshold level clinical sterility exists. Accordingly, some degree of inadequacy on the part of one mate may be offset by a high potentiality on the part of the other.

In analyzing a series of 65 cases primarily referred as gynecologic problems, we found that the major responsibility occurred in the female in 21 instances and in the male in 17, and that there were important etiologic factors in both in 27 cases. It is important to note that the husband was involved in two thirds of the cases.

In the past much attention has been given to the woman from the point of view of obtaining accurate diagnosis and providing therapy; comparatively little

attention has been given to the same problem in the man. However, in view of the recently recognized high incidence of masculine abnormalities, investigation and therapy of the man must be adequately correlated with the diagnosis and treatment of the woman.

SPERMATOGENIC PHYSIOLOGY

Spermatozoa are produced in the seminiferous tubules of the testes under the stimulative influence of pituitary gonadotropic hormones. According to current theory, the so-called follicle-stimulating fraction of the anterior pituitary stimulates sperm development and the luteinizing factor causes the testicular interstitial tissue to produce male hormone. Male hormone acts on the accessory sex glands, stimulating their activity and external secretion.

Mature sperm develop from primitive spermatogonia which pass through the stages of primary spermatocyte, secondary spermatocyte and spermatid in the process of maturation. The successive stages of development proceed from the periphery of the tubule to the center of the lumen, so that when the spermatozoa are developed they are released into the lumen and transported through the efferent ductules into the epididymis. The epididymis serves as a storage place for sperm, where they apparently ripen and become fully mature. Many investigators believe that the further maturing of the sperm in the epididymis endows them with independent motility. Semen, at ejaculation, is a mixture of sperm with the secretions of the epididymis, vas deferens, seminal vesicles, prostate, bulbourethral gland and urethral gland. The bulk of seminal secretion generally comes from the prostate.

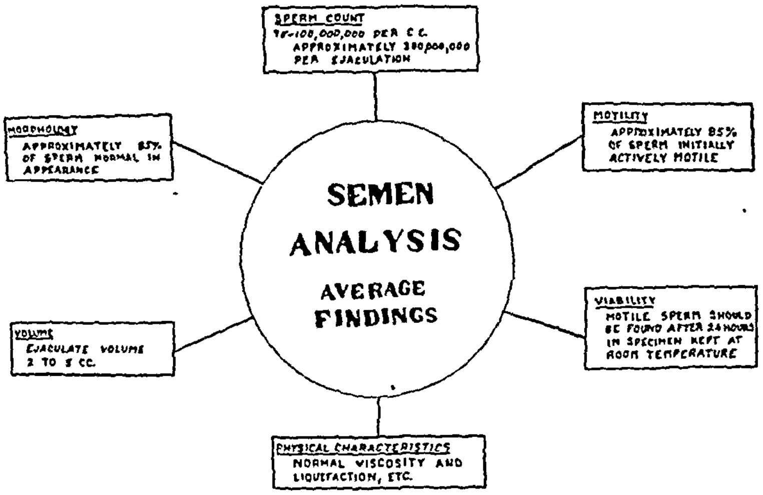
Little is known concerning the time required from the onset of development of sperm as spermatogonia to their appearance in the ejaculate. No significant data are available for human beings. In the guinea pig, however, Toothill and Young[4] deduced that fourteen to sixteen days were required for sperm to traverse the male tract. Whether a similar time interval is necessary in man is a question. Numerous reports have suggested extremely prompt therapeutic responses, which, however, could conceivably be explained by an emptying out of the more distal portions of the tract under the stimulation of treatment.

SEMEN REQUIREMENT FOR FERTILITY

There is much conjecture as to what constitutes an adequately fertile specimen of semen. Arbitrary average standards have been set, and we know that many fertile males produce semen which falls into this category (fig. 1). It is generally accepted that a normal specimen of semen will contain a volume of 2 to 5 cc., a count of 75 to 100 million spermatozoa per cubic centimeter, with approximately 85 per cent normal morphologically (figs. 2 to 6) and 85 per cent actively motile. The specimen will be of an arbitrary normal viscosity and should liquefy readily. How far a specimen may deviate from these standards and still be fertile is, of course, not known. It is logical to assume that there can be no hard and fast criterion, since much will depend on the fertility level of the partner.

Whether nature has been needlessly abundant in producing so many million sperm per ejaculate to fertilize but one egg is still a philosophic question. However, more and more evidence seems to indicate that a fairly large number of sperm are required to reach the egg before fertilization will occur. The work of Rowlands[5] and others on hyaluronidase gives support to the view that some enzyme such as hyaluronidase is transported by the sperm to the egg, and must be present at the site of fertilization in adequate amounts to facilitate penetration of the egg. There is support of this view in observations on lower animals, in which a large excess of sperm is known to be needed for fertilization; this has been shown by A. Tyler[6] to be due to the necessity for neutralizing excess specific egg substances present in the medium.

Some investigators have reported the occurrence of fertilization when the semen specimens have been quite subnormal. Hotchkiss,[7] for example, has reported the occurrence of pregnancy, using centrifuged insemination specimens, in an instance in which the count was as low as 6.5 million per cubic centimeter. In a few cases we have utilized for artificial insemination specimens of the husband's semen which were about 50 per cent below average and have obtained pregnancies. In view of this it is important to get the maximal improvement obtainable in even apparently hopeless cases, for it is impossible to predict when a relatively poor specimen may prove effective.



SPERM COUNT
75-100,000,000 PER C.C.
APPROXIMATELY 300,000,000 PER EJACULATION
MORPHOLOGY

MOTILE SPERM SHOULD BE FOUND AFTER 24 HOURS IN SPECIMEN KEPT AT ROOM TEMPERATURE
PHYSICAL CHARACTERISTICS
NORMAL VISCOSITY AND LIQUEFACTION, ETC.

Fig. 1.—"Normal" standards for semen in fertile persons. Specimen should be collected in clean glass container after three or four days' continence and preferably examined within an hour of ejaculation. At least two specimens should be evaluated.

CORRELATED THERAPY

Theoretically, there are only about thirteen days in the year when the average woman may conceive. By most recent estimates, the life of the unfertilized ovum after extrusion is probably no more than twenty-four or forty-eight hours. Some investigators have even stated that the actual length of time during which the ovum may be capable of being fertilized is only a period of several hours. In view of this fact any therapy of sterility must take into account the necessity for providing an adequate specimen of semen at the approximate time of ovulation.

It is highly important, therefore, to determine the time of ovulation as accurately as possible and to make every effort to obtain the maximal quality of semen at that time. Various technics have been employed to determine the time of ovulation. These include the analysis of daily vaginal smears, sequential endometrial biopsies, electrometric recordings and pregnandiol determinations. Undoubtedly the most practical method currently available is the study of basal body temperature (that is, the daily temperature taken on awakening and prior to any activity). Tompkins,[8] Rubenstein,[9] Zuck,[10] Greulich[11] and others have reported in detail concerning the relation of basal temperature curves to ovulation. In general it may be said that the daily basal temperature curve during the normal ovulatory menstrual cycle is a diphasic one (fig. 7). During the first half of the cycle the temperature tends to fluctuate at a low level. Near midcycle there may be a dip followed by a rather precipitous rise, and in the second half the temperature maintains a higher level and falls at about the time of menstruation. Should pregnancy intervene the higher level is maintained. At exactly what point in the tracings ovulation can be assumed to occur is still an undecided question. Some investigators believe that it takes place at the point of the drop which precedes the rise. Others have reported that ovulation does not occur until immediately after the temperature has started to rise. Greulich,[11] for example, in an interesting investigation noted the temperature curves in a number of patients prior to pelvic operative intervention and then studied the development of corpus luteum as found at operation as a criterion of when ovulation had occurred. He concluded that ovulation does not take place until after the temperature rise occurs.

Fig. 5.—Normal and abnormal forms: (1) two nuclei; (2) double head; (3) normal, and (4) abortive.

By the observation of tracings of given patients over a period of a few months one may form a reasonably accurate estimate of the average time of occurrence of ovulation in that particular patient. The timing of coitus relative to ovulation depends on the speed of travel of sperm and egg and their periods of viability. Roughly it may be estimated that coitus approximately twelve hours after actual ovulation would be well timed.

That pregnancy does ensue on occasions when the apparently fruitful coitus has taken place several days distant from the theoretic time of ovulation is undoubtedly true. In such instances it is conceivable that under certain circumstances spermatozoa may remain viable and maintain their fertilizing capacity for several days in the fallopian tubes. It is also conceivable that the ovum at times may remain in the tubes and be capable of being fertilized for several days beyond the average.

However, in dealing with infertile patients it is reasonable to assume that the most we can hope for is the average physiologic relationship. Therefore it is important that the best specimens of semen be obtained at the time of ovulation. Since in many instances we are dealing with husbands whose semen potentialities may be relatively low grade, management of the husband should be correlated with the wife's cycle.

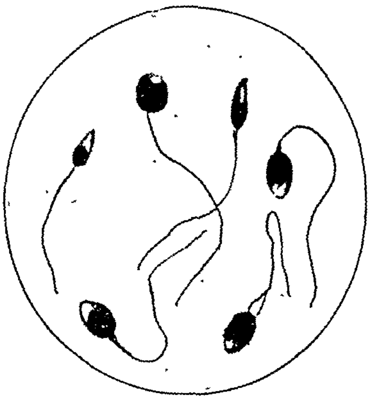

Fig. 6.—Normal sperm, anteroposterior and lateral views.

With such correlation in view, it is best to follow certain general rules. For example, to avoid wasting a possibly good specimen, it is not sound to perform semen analysis a few days, or even three or four days, before ovulatory time unless the specimen is to be used for artificial insemination. A good specimen may otherwise be wasted, and in a male with relatively low fertility the ability of quick regeneration is not to be expected. In the normal male the spermatozoa are rapidly and readily regenerated, and it is generally believed that emptying of the epididymis and other factors furnish additional stimulation for production of sperm, but this stimulation is probably not adequate in the abnormal case. It is preferable to take semen specimens for evaluation purposes at about the time of onset of the wife's period. In that way there is a considerable interval of time during which spermatic regeneration may occur. For the same reason it is advisable to restrict coitus to those days of the month which would theoretically be most likely to prove fruitful.

Relative to artificial insemination using husband's semen, it should be stated that this procedure is of conjectural value except in a few specific instances in which delivery is faulty, or in situations in which one wishes to evaluate specimens at the time of ovulation.

The treatment of male infertility requires careful attention to general health and well-being as well as to therapy designed toward correcting any genitourinary pathologic conditions. Satisfactory improvement often follows regulation and improvement in dietary habits; regulation of working hours; avoidance of fatigue and strain, both physical and mental; improved program for recreation and exercise, and avoidance of excessive smoking and use of alcoholic beverages.

[11] Greulich, W. W.; Morris, E. S., and Black, M. E., in Proceedings of Conference on Problems of Human Fertility, 1943, p. 37.

Various pharmaceutic agents have been used in attempting to improve the quality of semen in cases in which there is no tubular obstruction and in which gonadal atrophy, if present, is incomplete. Theoretically, pituitary gonadotropic preparations would afford the most effectiveness, but unfortunately the therapeutic results from these substances are inconsistent and often disappointing. Many of the so-called pituitary preparations on the market are those of chorionic gonadotropin which contain essentially the luteinizing fraction. These would not be expected to have much effect on sperm production. Whatever effect they might conceivably have on semen could be mediated through the testicular interstitial tissue and production of male hormone. The latter seems to be an important agent in maintaining sperm motility, possibly indirectly through the accessory sex glands.

There are a few preparations which are said to contain fairly substantial amounts of follicle-stimulating hormone. It is our opinion, however, that all these preparations in moderate dosage are weak. In utilizing them in enormously high dosage we have obtained some satisfactory but limited results. Administration of a preparation of equine gonadotropin[12] in daily dosage of 4 to 5 cc. for two week intervals has apparently furnished definite stimulus to spermatogenesis in a few instances. For example, in a man aged 56 whose sperm count on several occasions showed a low concentration and a low motility, a dosage of 5 cc. daily brought the count up to 123 million per cubic centimeter with 50 per cent motility following one 2 week cycle, and then with the addition of a little methyltestosterone and prostatic massage over another two week cycle the semen increased to 183 million per cubic centimeter with 75 per cent motility. In a patient of this type who is certainly not in the age group of maximum fertility it seems fairly reasonable to credit the treatment with the degree of improvement observed. However, it must be emphasized that such therapeutic effectiveness is the exception rather than the rule. Our series with this preparation is as yet too small to permit an accurate evaluation or any recommendation of its use, but the results thus far would appear to justify further experimentation, especially if more potent material becomes available.

In certain patients male hormone may be of value in improving sperm motility. The use of small doses, such as 5 mg. of methyltestosterone daily by mouth; coincidental with gonadotropic therapy helps attain some degree of improvement in motility. In large doses testosterone is said to depress spermatogenic activity through its inhibitory effect on the pituitary.

Many other agents have been utilized in treating seminal inadequacy. Thyroid, for example, has long played an important role and in instances in which there is some evidence of subnormal metabolism may prove useful. However, its administration should be limited to those persons who are thyroid deficient because continued use of it by patients with normally functioning thyroid glands may ultimately cause depression of their own thyroid activity, as pointed out by Farquharson,[13] Shelton[14] and others.

Amino acids, notably arginine, appear to be valuable as adjuvant therapy. It has been demonstrated by Shettles,[15] Zittle[16] and other investigators that this substance is an important constituent of the sperm head. Shettles found that even a temporary deficiency of arginine in the diet may cause pronounced disturbances of spermatogenesis in human beings. If there is evidence of nutritional inadequacy a suitable amino acid concentrate should be prescribed.

Vitamin B complex apparently plays an important role in sperm metabolism, although the details of this are not completely known. Biskind and Falk[17] have reported a good percentage of successful results in utilizing vitamin B complex in therapy of seminal inadequacy. A dosage of 50 mg. of thiamine daily with crude liver extract and other factors of the B complex was employed in a recently reported series.[18] MacLeod[19] considers vitamin B complex one of the most important medicaments that can be given to improve sperm motility.

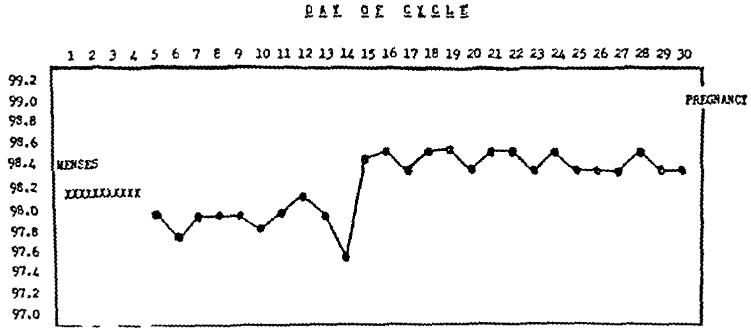

Fig. 7.—Basal temperature curve in an ovulatory menstrual cycle during which pregnancy occurred. Note low level during preovulatory phase, precipitous rise at ovulation and high postovulatory level. With pregnancy the higher level is maintained.

Pregnenolene, an intermediary in the production of progesterone from cholesterol, has been found to stimulate spermatogenesis in lower animals. We have used it experimentally in a daily dosage of 50 mg., but results as yet are inconclusive.

Another therapeutic adjuvant is the use of the dextrose-Ringer's douche. MacLeod has shown that spermatozoa metabolize dextrose for motility. Hotchkiss and MacLeod[20] reported a series of infertile cases in which the use of a buffered Ringer's-dextrose douche shortly before intercourse appeared to be the one factor which brought about pregnancy in a substantial percentage of difficult cases in which etiologic factors were vague. The Ringer's-dextrose douche has more physiologic basis than the older alkaline douche and is used as a routine procedure by many investigators.

CONCLUSION

The problem of sterility need not necessarily be one for the specialist. True, a certain percentage of patients will present pathologic conditions that require treatment and observation by the gynecologist or the urologist, but there are indeed a fair percentage which can be handled by the general practitioner who is willing to devote the time and careful study required.

The masculine role has been purposefully stressed in this study of infertility in an effort to emphasize that the husband is probably at fault nearly as often as the wife and merits more than the cursory attention which is so often given.

ABSTRACT OF DISCUSSION

Dr. Walter W. Williams, Springfield, Mass.: The adequate staining of a specimen of spermatozoa of a sperm population, contrary to the general belief, is easily done in around three to five minutes. In a pathologic specimen of semen one sees the shadow of the centrosomic material in the base; there is a narrow nucleus, and at times a small cell which is pathologic. The general picture is quite different from the normal. The essentially normal cell, shows the neck, the body, the nucleus, the centriolar mass and the acrosome. A cell of this nature rotates, so it is difficult to get the cellular morphology. In the examination of semen occasionally double forms are described. Usually they are due to a lack of the development of the centriole in which the cells do not become separated during the last stages of spermatogenesis. The actual filament, the narrow nucleus and the enlargement of the middle piece are all readily observed with a properly stained specimen. A cell with a lack of acrosomic development is ordinarily called a round cell. In spermatic dysplasia or hyperplasia, in many instances the germ plasm is severely diseased and if stimulation of the germ plasm is attempted there are fewer spermatozoa and the quality becomes poorer. The germ plasm is not in fit condition to function.

Dr. Fred A. Simmons, Boston: I congratulate Dr. Tyler for his fine presentation. However, I do not think it would be fair for a group of specialists to leave this room with the idea that testosterone or gonadotropin have any place in the treatment of the average sterile man or woman. I have seen patients in the East who have been treated by the family physicians and by specialists with these hormones, and, as far as I can make out from the off-the-record remarks of persons who worked in the laboratories where these hormones are used, there is no place for them at the moment in the average case of sterility. Dr. Tyler mentioned therapeutic agents, and I think he probably would agree that the most valuable therapeutic agents in the treatment of the infertile male are things in the hands of all practitioners. The sterility problem is no mystery. All you have to do is spend the time on it. The agents which I would suggest as adjuncts to the measures already outlined would be the denial to the husband of the use of tobacco in any form or the use of alcohol in any form, an adequate high protein diet, an adequate amount of exercise, particularly in those men who may have been active in exercise in college or high school days, a degree of continence and reduction in the frequency of intercourse as the fertile time is approached. Physicians doing this work often get patients who are told they are sterile. If the physician is not interested in this subject, let me suggest that the patient be sent to someone who is. Don't make the mistake of telling him, "In two or three years you will probably have a baby. If not, come around." The thing to do is to get a specimen, and if that is not normal on two occasions and you don't want to treat the patient, send him to someone who knows how. If you do want to treat him, then pay attention to what Dr. Tyler said to you this morning.

Dr. Edward T. Tyler, Los Angeles: The sperm morphology is an extremely important factor. I cannot say that the staining and observation of these smears is simple. It is time-consuming. It takes a good technician quite a while to master the technic of making a smear that is not full of extraneous material, in which one can actually observe some real distinctions in the spermatozoa. When the technician is familiar with the procedure of demucifying the slides and so forth she is able to do it rather rapidly. I agree with Dr. Williams on the importance of morphology. I hope I haven't left you with the thought that pituitary gonadotropins are the things to use. Most of these preparations that have been used are ineffective. I qualified my remark by saying that this particular preparation which we have been using has only been used in relatively few cases. I do say, however, that when we have tried heavy dosage on some of these patients, while the percentage isn't high we occasionally have gotten a successful result. The only reason I recommend trying it in certain cases is because one's hands frequently are so tied that one is willing to try anything, and if this preparation has any possibility of working, I believe it is worth a trial if the patient can afford it. In a few cases it has apparently helped. But we do not consider that there has been enough success to recommend this agent. Another point which I should have emphasized was all those factors which Dr. Simmons stressed and which probably are more important than anything else, namely, general health, exercise, restriction of alcohol, if that seems to be a factor, and prostatic massage, which is extremely useful. It is done particularly in cases in which sperm motility remains low. Prostatic massage is given about three times a week routinely.

Dr. L. C. Burwell, Los Angeles: I should like to have Dr. Tyler elaborate more on the use of tobacco. Abstinence for how long? And should it be abstained from by only the man or both the man and woman?

Dr. Edward T. Tyler, Los Angeles: I think if you can secure abstinence from tobacco for the duration of the time you are observing the patient, that is the best. We have had a few patients who were chain smokers; where we believe that tobacco alone was the factor which was depressing their semen. If one is going to have them abstain, the point is to keep them off it right along. Sometimes you don't get cooperation. I remember 1 patient for whom we tried everything and he was taking a lot of alcohol. He seemed to think he needed it to keep him going in his work. We agreed to let him go for a while without depriving him of alcohol, because we knew if we told him he would have to stop drinking we wouldn't get anywhere at all. After a short while we decided that there was no use in temporizing any longer. We asked him definitely to stop drinking completely. Whereupon, we didn't see him again. I think in some of these cases the physician has to try to do the best he can with the patient, but the actual importance of these things can't be overstressed.

Dr. L. C. Burwell, Los Angeles: How about the effect of nicotine on the ovum?

Dr. Edward T. Tyler, Los Angeles: It is difficult to determine in mammals, because it is so difficult to get mature ova from these experimental mammals. One certainly could tell something about it in invertebrates, from which eggs are readily obtained, but whether results can be transposed from invertebrates to mammals is questionable. I don't think it has been feasible from a technical point of view to observe any results directly on the ovum.

Agricola, Paracelsus and Occupational Medicine.—Nearly twenty years after Paracelsus sent his manuscript on mining diseases to the public authorities for their approval of its publication—he never received an answer or heard of it before his death—and twelve years before it was published by a faithful follower from the long-hidden sheets, there came out in 1556, from the famous press of the old friend of Paracelsus at Basel, Froben, a book, "De re metallica," on mining. Its author, George Agricola, like Paracelsus a physician but more famed as a chemist and technologist, raised himself with this book to the foremost place as a mining expert of greatest authority, and for scores of years the book kept the rank of the encyclopedia of mining. . . . In spite of all the injustice, ignorance and enmity which Paracelsus met with, his pioneer work in the field of occupational diseases never was disputed.—Frankel, Walter K.: Paracelsus, the Founder of Occupational Medicine, *Occupational Medicine,* March 1947.

CESAREAN HYSTERECTOMY

RALPH A. REIS, M.D.
and
EDWIN J. DeCOSTA, M.D.
Chicago

This study was undertaken to determine the present status of cesarean hysterectomy. An operation originally devised to combat postcesarean infection and hemorrhage, its indications have gradually been widened to include many conditions for which removal of the uterus is necessary or desirable. In 1876, Porro[1] extirpated the gravid uterus for the avowed purpose of reducing the frightful mortality then associated with cesarean section. Due credit must be given Porro's carefully planned effort because in 1874, experimenting with pregnant rabbits, he demonstrated the feasibility of this procedure.

However, Porro was not the first to consider or the first to perform cesarean hysterectomy. In 1768 Cavallini[2] made the statement that "all things having been duly weighed, I do not doubt that the uterus is not at all necessary tó life, but whether it may be plucked out with impunity from the human body we cannot be certain without a further series of experiments of this kind which perhaps a more fortunate generation may obtain."

In 1809 Michaelis[3] of Marburg pointed out that "when in ignorance the uterus has been cut away, the reaction has been much less. It is indeed a question whether cesarean section would not be made less dangerous if with it were combined the extirpation of the uterus, an organ which is, after all, under such circumstance nothing but harmful." Blundell in his lectures at Guy's Hospital in 1828 said, "In speculative moments I have sometimes felt inclined to pursuade myself that the danger of the cesarean operation might be considerable diminished by the total removal of the uterus. Perhaps this method of operating may prove an eminent and valuable improvement." Blundell[4] also described the survival of 3 out of 4 pregnant rabbits in which the uterus had been extirpated.

Actually the first cesarean hysterectomy was reported by George H. Bixby[5] in 1869 in an article entitled "Extirpation of the Puerperal Uterus by Abdominal Section." The patient was operated on by H. R. Storer because of dystocia arising from a pedunculated and adherent fibroid. The cesarean section was followed by hysterectomy because of uncontrollable bleeding. The cervical stump was sutured to the lower part of the abdominal incision; the patient died in seventy-eight hours.

This operation is cited by Porro, who described a technic similar to that used by Storer. At first Porro's proposal was received with disfavor in spite of the fact that his patient survived. Undaunted by the failures of several Italian obstetricians, Spaäth and Carl and Gustave Braun adopted this procedure. Compared to the almost 100 per cent mortality of the classical cesarean operation at that time, their results were startling and encouraging.

In 1880 Isaac E. Taylor[6] reported the second American case in which the patient was operated on early and "by the method of Lister." The pedicle was dropped in the pelvis and no drains were employed. Unfortunately this patient died on the twenty-sixth day of embolism following phlegmasia dolens. Eighteen days before Taylor, Veit,[7] of Bonn, employed the same technic of returning the pedicle to the pelvis. His patient also died. The same year Robert P. Harris[8] analyzed the 50 known operations of hysterectomy following cesarean section and reported a 58 per cent mortality. By 1883 the total reported cases numbered 134. These were summarized by Clement Godson.[9] Godson made two improvements: (1) He used a transverse incision of the lower portion of the uterus for removal of the baby and (2) he left the placenta in situ. He compared intraperitonealization and extraperitonealization of the uterine pedicle and showed that intraperitoneal placement of the stump was associated with a 77 per cent mortality against a 53 per cent mortality for extraperitoneal placement.

The basic premises of the operation described by Porro include (1) the complete ablation of the uterus and its appendages accomplished by the use of some type of occluding ligature, often metallic; (2) the external placement of the uterine pedicle, and (3) the employment of cul de sac and/or abdominal drainage. These technical procedures are mentioned only because cesarean hysterectomy now differs so greatly from that originally proposed. In the first 50 cases reported, only the first was performed by Porro, but due credit must be given him because his patient survived and through his writing the world learned of a new and valuable procedure.

Almost coexistent with the introduction of cesarean hysterectomy came the new concept of infection, surgical technic and cleanliness. In evaluating the statistics compiled before 1870, as compared with those after that date, it becomes difficult to decide whether the new found knowledge concerning infections, plus newer concepts of physiology, may not be as important as the procedure recommended by Porro. Physicians and surgeons in practice today are apt to forget that for the period of one hundred years preceding 1876 the mortality associated with cesarean section in such institutions as La Maternité in Paris and the Lying-In of Vienna approached 100 per cent. They also forget that it was not common practice to suture the wound in the uterus. It is surprising that any patient should have survived rather than that so many died. It was not until 1880 that Max Sanger introduced the use of a large number of sutures, deep and superficial, in the uterus in order to secure a complete closure and thereby control hemorrhage and prevent the lochia from draining into the peritoneal cavity. This operation effectively reduced the mortality of the cesarean section and competed with the increasing popularity of the

Porro section, introduced but a few years before. It is also impossible to comprehend why there was open antagonism to the use of uterine sutures, but opponents such as James Edmunds[10] were vociferous as late as 1902. Until the middle of the nineteenth century, although cesarean section had been known and practiced on living women for two hundred and fifty years, suturing had been employed on only four occasions.

On the twenty-fifth anniversary of Porro's original paper, a monograph was published in Rome, "L'Operazione Cesarea,"[11] with detailed statistics on the 1,097 operations reported as of that date, showing a mortality of 24.8 per cent. In the year of the publication, 1901, the mortality was 18.1 per cent. As had been originally urged by Harris[12] in 1880, efforts were made to perform the operation earlier, and the mortality was decreasing.

Total	16	16	12	4	6	54

Porro recommended hysterectomy whenever cesarean section was indicated. With improvements in surgical technic, the introduction of uterine sutures and aseptic precautions, it seldom was necessary to remove the uterus. During the subsequent decades intrapartum infection became the most important reason for performing cesarean hysterectomy. In 1921 Williams[13] stated that "the prime indication is cesarean section late in labor, particularly when signs of intrapartum infection are present." Today, however, as shown by Briscoe,[14] infection is not the commonest cause for cesarean hysterectomy. Low cervical or extraperitoneal cesarean section is often the procedure of choice when abdominal delivery is advisable and intrapartum infection is present.

In the recent writings of Phaneuf,[15] Lash and Cummings,[16] Lazard,[17] Gustafson,[18] Wilson[19] and others the following indications are considered: (1) intrapartum infection when abdominal delivery is indicated; (2) uterine hemorrhage, uncontrollable after cesarean section, premature separation of the placenta and placenta previa; (3) uterine fibroids; (4) rupture of the uterus; (5) carcinoma of the cervix; (6) placenta accreta; (7) cervical or vaginal stenosis; (8) pulmonary tuberculosis; (9) chronic nephritis, and (10) as a method to effect sterilization.

In our series of 54 patients, uterine fibroids (25) are the prime indication (table 1). In 11 of these 25, the fibroids were uncomplicated but of such number, location or size that it was felt safer to perform an elective cesarean hysterectomy at term than to permit the patient to labor and subject her to a subsequent hysterectomy. Six women with fibroids had had a previous cesarean section; 3 had fibroids and prolonged labor; 2 had fibroids obstructing the birth canal, and in 3 others fibroids were associated with toxemia or placenta previa.

Cesarean hysterectomy was performed in 15 patients for uterine bleeding. Of these 6 had uncontrollable bleeding at the time of cesarean section, 5 had abruptio placentae, 3 had placenta previa and 1 had a placenta accreta. The operation was performed four times for preeclamptic toxemia and only four times for intrapartum infection. The remaining 6 women had cesarean hysterectomy for as many miscellaneous reasons, only one hysterectomy being for sterilization. In 1921 Williams advocated cesarean hysterectomy as the operation of choice when cesarean section was performed the third time. Fifteen in his series of 57 were performed solely to effect sterilization.

Although Phaneuf[20] expressed the opinion that there still is a place for the operation when pregnancy is associated with fibroids or placenta accreta, he stated that in recent years the number of hysterectomies following cesarean section is decreasing.

In 1922, J. W. Harris[21] reported an incidence of 28.7 per cent for cesarean hysterectomy with cesarean section at Johns Hopkins Hospital, while from 1932 to 1942 Monahan[22] reported only 11.3 per cent from the same hospital. At Michael Reese Hospital, as reported by Stein and Leventhal,[23] for the period 1922 to 1927, the incidence of cesarean hysterectomy was 0 per cent, while in the period 1928 to 1932 it was 1.65 per cent. With the current increased popularity and safety of the cesarean section and the broadening of the indications, one might expect the incidence of cesarean hysterectomy to show a relative decrease. Our study indicated that this is not the case. At present at Michael Reese Hospital the incidence of cesarean hysterectomy–cesarean section is 4.5 per cent.

The age of the patients varied from 24 to 41, with 32 patients more than 34 years old. Relationship of age and parity is given in table 2. The average age was 34.2 years. It will be noted that hysterectomy was performed sixteen times in primiparas. Over half of these patients were more than 34 years old. The indication was fibroids in 12 of the 16, revealing that as older women become pregnant, pregnancy is more apt to be complicated by conditions arising in the older age group.

The American literature for the period 1931 to 1945 includes reports of 731,690 deliveries in which the incidence of cesarean section and of cesarean section with hysterectomy is also given. For obvious reasons this survey is not complete, because reliable statistics are limited to the larger maternity hospitals and teaching institutions. However, by including reports from various sections of the United States, state survey reports and smaller hospital reports, one can determine a fairly accurate incidence of cesarean section during the years 1931 to 1945.

				731,690	25,027	3.42	2.14	5.56	636	2.54	5.2

Table 3 is the result of this study. In the 731,690 deliveries the incidence of cesarean section is 3.42 per cent. It will be noted that generally where the cesarean incidence is up the mortality is down, and vice versa. This leads to the observation that the sum of the incidence percentage and the mortality percentage gives a fairly constant figure, which can be expressed as 6.0 plus or minus 2.0. The only real exception to this constant comes from Los Angeles, where the reported incidence of cesarean section is high. The over-all average maternal mortality for cesarean section in the United States is 2.14 per cent.

There are 25,027 cesarean sections reported, and hysterectomy was performed six hundred and thirty-six times, once in every 39 cesarean sections, an incidence of 2.54 per cent. This represents 1 cesarean hysterectomy in every 1,150 deliveries. The average mortality is 5.2 per cent.

In our series cesarean hysterectomy was performed in 54 of 1,202 cesarean sections, an incidence of 4.5 per cent. There were, during this period, 23,214 deliveries, the incidence of cesarean section being 5.18 per cent. Three patients died after cesarean section, an incidence of 0.25 per cent. However, there were no deaths in the last 675 cesarean sections, covering a period of six years. There were no deaths following cesarean hysterectomy.

Twenty-one of the 54 patients had a temperature of 101 F. or over, exclusive of the first twenty-four hours. In 1 patient a pelvic abscess subsequently developed which was drained vaginally. This morbidity rate is less than that following cesarean section. Removal of the uterus removes the potentially infected thrombotic area of placentation, sloughing of the decidua is eliminated, involution of the uterus is eliminated and a short incision with opportunity for spontaneous drainage is substituted for the longer buried uterine incision.

Five babies were stillborn, all associated with abruptio placentae. One liveborn infant died on the second day; the mother had preeclamptic toxemia.

Less difficulty should be encountered in cesarean hysterectomy than in the usual abdominal hysterectomy because of the greater mobility of the uterus. We distinguish between "elective" cesarean hysterectomy and "nonelective." In the former, removal of the uterus is anticipated prior to its incision, while in the latter hysterectomy becomes a necessary procedure during the course of the operation. We routinely perform the typical laparotrachelotomy with longitudinal incision of the lower uterine segment. For the elective cesarean hysterectomy the procedure is identical except that after the reflected peritoneum has been freed a transverse incision in the lower uterine segment is substituted for the longitudinal incision.

The baby is delivered through this transverse incision in the lower uterine segment. The umbilical cord is clamped and ligated, and the placenta is allowed to remain in situ. The broad ligament and tube, together with the round ligament and the suspensory ligament of the ovary on each side, are doubly clamped and cut. A second pair of clamps catch the broad ligaments down to the level of the uterine vessels, which are readily accessible because of their upward displacement by the pregnancy. The uterine vessels are clamped and cut. The transverse uterine incision is then carried posteriorly and the amputation of the uterus is completed. The walls of the lower uterine segment are approximated by a continuous interlocking stitch. The uterine arteries are ligated separately, and the uterine ligament stumps are ligated. The peritoneum of the bladder is sutured to the peritoneum of the posterior surface of th [illegible] and to the cervix to effect complete [illegible]

When hysterectomy is indicated after the laparotrachelotomy with its usual longitudinal incision, the technic is the same except that amputation of the uterus is begun at the junction of the lower third and the middle third of the longitudinal incision. The lowest portion of the longitudinal uterine incision must be sutured before the transverse lower uterine edges can be approximated.

SUMMARY

A review of 731,690 deliveries as reported in the American literature for the years 1931 to 1945 establishes the incidence of cesarean section as 3.42 per cent (25,027 cesarean sections) and the maternal mortality as 2.14 per cent. Of these 25,027 cesarean sections, hysterectomy was performed in 636 instances, an incidence of 2.54 per cent, and was associated with a maternal mortality of 5.2 per cent.

In the Department of Obstetrics of Michael Reese Hospital there were 1,202 cesarean sections (an incidence of 5.18 per cent). During the years 1933 to 1945 hysterectomy was performed fifty-four times (an incidence of 4.5 per cent). The maternal mortality associated with cesarean section was 0.25 per cent, and with cesarean hysterectomy, zero.

Cesarean hysterectomy is technically not difficult. In elective cesarean hysterectomy the morbidity and mortality should not exceed that of simple hysterectomy.

The most frequent indications include pregnancy associated with fibroids, antepartum hemorrhages, uncontrollable bleeding at the time of cesarean section and intrapartum infection. Of these, the least frequent indication in our series has been intrapartum infection.

104 South Michigan Boulevard.

ABSTRACT OF DISCUSSION

Dr. Donald G. Tollefson, Los Angeles: Dr. Reis and Dr. DeCosta have given us an excellent summary of the history of cesarean hysterectomy. Their report indicates that the incidence of this operation has been increasing, while the literature states that it is on the decrease. Chemotherapy and extraperitoneal types of the procedure, as recommended by Waters, Cartwright and others, probably account in a large part for this decrease. Their series shows that only 1 hysterectomy was done for sterilization, while Williams gave this indication in over 25 per cent. The surest method of sterilization is hysterectomy, and the only controversies are whether the uterus has some endocrine factor and whether the psychologic factor of absence of menses is a contraindication. While one may not be justified in taking out a normal uterus, is a uterus with several scars to be considered normal? The frequency with which menorrhagia and metrorrhagia occur in the late thirties would seem to warrant the consideration of hysterectomy in this particular age group. Tubal sterilization is not technically such a simple procedure and the morbidity is often considerable, while the procedure of cesarean hysterectomy is easier than hysterectomy in the nonpregnant state. The low mortality as reported by Dr. Reis and Dr. DeCosta is commendable. I should, however, be most interested in reviewing the total maternal and fetal mortality of the entire series of over 730,000 deliveries before I am convinced that a high incidence of cesarean section is excessively dangerous or the principal cause of high maternal mortality. It is not only the operation, but also the condition for which it is done which is responsible for the mortality. It would seem proper to mention a series from Los Angeles to defend the high incidence of cesarean sections in this area referred to by the authors. In the California Lutheran Hospital during the past seventeen years, 22,068 patients were delivered with 1,692 cesarean sections, an incidence of 7.65 per cent and a mortality of 1.1 per cent. The total maternal mortality was only 0.158 per cent. In the past eleven years there were 74 cesarean hysterectomies with 1 death included in this series. At the Good Samaritan Hospital, in twenty years, Dr. Fagan has recently reviewed 14,695 deliveries, with 1,732 cesarean sections, an incidence of 11.78 per cent, with a mortality of 1.15 per cent, but the total mortality in this group was 0.19 per cent. We shall defend our position of high incidence in Southern California on a low fetal and maternal mortality.

Dr. Emil J. Krahulik, Los Angeles: Many patients registering for repeat cesarean section will desire sterilization. Some will present a history of menorrhagia, dysmenorrhea or other symptoms, aside from more definite anatomic pathologic conditions, such as fibroids and retroversion. These patients are candidates for future abdominal operations. When we encounter a patient who already has had tubal sterilization, she will embarrass us by wondering whether this additional trip to the hospital might not have been avoided. Cesarean hysterectomy may appear radical. Not until one realizes that one is permanently relieving the patient of some previous complaints will one be able to admit the existence of actual indications. Will extirpation of the uterus initiate a chain of symptoms resulting from artificial menopause? This point is now undergoing an evaluation. Those who have been doing cesarean hysterectomies are convinced that symptoms of even minor moment are encountered only rarely. Technically the operation is easy, and the time consumed is no greater than would be required to excise a portion of each tube and carefully peritonealize the areas. The frequency of the usual postoperative complications is smaller than usually encountered in cesarean section with or without sterilization. Dr. Reis draws attention to the high incidence of cesarean section in the Cedars of Lebanon Hospital in Los Angeles. The number of deliveries is 9,022, and the mortality is 9, or 1 per thousand. Included in the 9,000 are 807 cesarean sections, or an incidence of 9.6 per cent. There were no deaths in the cesarean group. Sixty-seven were cesarean hysterectomies. Eight were done as definite emergencies encountered during the operation, while 59 were planned-for hysterectomies. This report is from a private hospital, staffed almost entirely by board members, and neglected or mismanaged cases are rare. In the Los Angeles County General Hospital, the patients have not always availed themselves of complete antepartum care and advice. The hospital also receives the neglected and mismanaged cases from the entire county. During the past ten years, there were 32,790 deliveries, including 1,092 cesarean sections, an incidence of 3.32 per cent. One hundred twenty-five were cesarean hysterectomies, 20 were done as emergencies and 105 previously planned. Many of these were bad risks to begin with, and 3 died.

Dr. Ralph A. Reis, Chicago: For the benefit of the audience, who may not know that the Civil War is over, I should say this is not a regional fight between Chicago and Los Angeles. The provocative sentence is as follows: "This leads to the observation that the sum of the incidence percentage and the mortality percentage gives a fairly constant figure which can be expressed mathematically as 6 plus or minus 2. The only real exception to this constant comes from Los Angeles, where the reported incidence of cesarean section seems too high." With that in mind, when the Secretary of the Section asked me whether I had any choice as to discussants, I picked our friends from Los Angeles, who have just spoken, not that I wanted them to defend themselves, but because I did want them to have an opportunity to hit back before this got into print. I do feel, and we all feel at Michael Reese Hospital, that when a woman is under 35, her uterus should be saved if possible; that unless there is an inherent pathologic condition of the uterus, there is no need, for carrying out a cesarean hysterectomy just for the purpose of sterilization. We do not do, and never have done in the last twenty-five years, cornual resections of any type. We do a simple "crush and ligature" which takes about thirty seconds for each tube. We do not feel that the uterus which is scarred by a lower uterine segment incision is a bad uterus, because when the lower uterine segment disappears after pregnancy, the scar disappears with it. It was impossible to do as Dr. Tollefson would have liked, and as he asked us to do, that is, to try to analyze mortality figures from the papers out of which we arrived at these 730,000 deliveries. It is almost impossible to take from the printed page any type of evaluation of the pros and cons of one procedure versus another. All we can do in the aggregate series is to give them to you as we found them and as we added them up on our adding machine.

PSYCHONEUROSIS, ITS SIGNIFICANCE IN GENERAL PRACTICE

RAYMOND W. WAGGONER, M.D.
Ann Arbor, Mich.

Factors in everyday life which resulted from the problems of war and now social, economic and personal unrest have led to a definite increase in individual emotional and psychologic difficulties. Even before the war studies in some general hospitals demonstrated the fact that a large percentage of patients had no physical basis for their symptoms. Surveys carried out in the military service have substantiated these observations. A large percentage, actually nearly three quarters, of the men rejected because of psychiatric difficulties by Selective Service were rejected for psychoneurosis. This is evidence of a tremendous amount of emotional maladjustment in a selected group of the population.

Contemporary papers on the subject indicate that at least one half of all patients have their symptoms as a result of emotional difficulties or that there is a sufficient overlay of emotional symptoms in addition to and as a part of the physical disease to warrant psychiatric understanding and treatment. When one considers that only about 2 per cent of the registered physicians in this country are trained in psychiatric procedures, it becomes obvious that these patients cannot be taken care of by psychiatrists. Therefore it is essential that every physician, whether he is in general practice or in a specialty, obtain some understanding of psychiatric principles and utilize these principles in the treatment of all his patients. The patient must be considered as a person who is ill and who has certain physical and emotional reactions to that illness, not just as a disease entity with no consideration of his way of thinking or feeling. "Here is a group of patients in which it is not the disease but the man or woman who needs to be treated . . ." (Francis W. Peabody[1]).

Problems involving the emotional and psychologic life of the patient can obviously be extremely mild or extremely serious, just as physical manifestations may vary in severity. The physician in general practice meets and treats all kinds of patient problems and this is, or should be, just as true of emotional illnesses or psychoneuroses as it is of any other type of illness. Clear understanding of the meaning of such symptoms and early proper treatment may prevent the development of serious manifestations.

No matter what the disease process, the person must have some sort of emotional reaction to his disorder if he is able to think or feel at all. Some approach illness in an apparently matter-of-fact manner, while others are extremely anxious, tense and disturbed over the possible seriousness of their condition. The person who must prove physical capacity to himself may find his emotional economy dangerously threatened by physical disease. On the other hand, the person who has reached the limits of his physical and emotional tolerance may welcome a physical disease as a means of relief from stress. Every patient will respond more promptly to treatment of any disease if the physician understands and adequately handles the emotional as well as the physical aspect of the illness.

A large percentage of patients who are sick have no physical cause for their illness, and yet the complaints and not infrequently the manifestations are of an organic nature. The physician who is satisfactorily practicing his calling must be aware of these possibilities and accept the challenge of carrying out a total treatment program. Unless the emotional problem is sufficiently complicated to require the service of a specialist, the physician who first sees the patient is the one who should treat the milder neuroses, which are characterized by anxiety, hysterical or conversion symptoms. Symptoms may simulate those of a relative with whom the patient identifies himself or toward whom he feels guilt. Sometimes the symptom is symbolic, such as the asthenia of the woman who wants to be cared for like a child, or the vomiting of a patient who rejects his sexual drives. Through psychogenic symptoms the patient often seeks to escape from an intolerable situation or to effect a compromise solution of an unconscious conflict.

During the past few years ever increasing attention has been paid to psychosomatic disorders. In a way the term seems unfortunate since it implies psychic and somatic difficulties rather than one disease process made up of thoroughly integrated psychologic, emotional and physical factors. Any bodily system may be involved with symptoms characteristic of dysfunction of the part, such as gastric ulcer, thyroid disease or hypertension. The specific localization and type of symptom in psychosomatic diseases is undoubtedly determined in part by constitutional factors such as a predisposition to allergic, vasomotor, cutaneous or other symptomatic disturbances, in part by accidental factors but largely by the experimental background and the type of stress affecting the person. Some interesting confirmatory manifestations occur in the course of psychotherapy. For example, a patient being treated by a dermatologist for excessive sweating of the hands and for psoriasis was referred for treatment of his emotional difficulties. During the course of treatment, when problems of strong emotional value were discussed his psoriasis would become much more pronounced. As the reaction to these emotional problems disappeared, the psoriasis improved and the excessive sweating dis-

Read before the Section on General Practice of Medicine at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

1. Peabody, F. W.: Doctor and Patient: Papers on the Relationship of the Physician to Men and Institutions, New York, The Macmillan Company, 1930.

appeared. Treatment of the emotional factors resulted in progressive improvement, although local treatment had been of little value. A patient with an unquestioned diagnosis of polycythemia vera showed variations in symptomatology during treatment which were difficult to explain on the basis of physical factors but were easily understood on an emotional basis. Many of his symptoms, which have been described as manifestations of polycythemia, had existed long before a diagnosis of this disease had been made and unquestionably were related to emotional factors. These improved when the emotional conflicts were resolved.

Common is the exaggeration of symptoms of a physical illness or a prolongation of the manifestations of physical illness on the basis of emotional needs of the person. The patient who has influenza followed by asthenia may by improper supervision or recommendations for rest from his physician have these symptoms continued over a much longer than necessary period of time. The patient is already conditioned to fatigue from physical factors. The infection or disease process produces a locus minoris resistentiae, and when unneeded rest or a vacation is prescribed the patient has a socially acceptable reason for a continued manifestation of symptoms. The result is an easier but decidedly unhealthy way for the patient to meet his life's problems.

Adequate rest is essential in certain diseases, but, as Menninger[2] has pointed out, unnecessary rest is harmful. I am convinced that more patients with cardiac disease are killed by the anxiety and emotional reactions stimulated by the physician who wants to insure adequate rest than by the disease process itself. One striking example of this sort comes to mind. A relatively young man who had an unquestioned coronary thrombosis, with electrocardiographic evidence of significant involvement of the cardiac musculature, was told by his physician that he must have many weeks of complete rest in bed. The danger of activity was overemphasized by this warning. After a few weeks he began to be depressed and was referred to a psychiatrist, who, recognizing the danger of the emotional reaction, began to get the patient up gradually. The emotional problems which had really precipitated his cardiac difficulty were resolved and in due course, in less than two years, as a matter of fact, the patient was again carrying on full activity. This was some six or eight years ago, and recently he has gone deer hunting.

The list of psychosomatic disease processes which have significant emotional factors is long and steadily growing. There is real danger in such patients that ill conceived and unwisely administered physical, medical or surgical treatment will lead to an intensification of the patient's symptoms.

Practical means of making the diagnosis and planning treatment must be available to the general practitioner and to specialists in fields other than psychiatry. It is hoped that some of the following suggestions may be of value. The physician should show interest in and obtain information about the patient other than that related to the immediate complaint. Of particular value is the description of the patient's adjustment to his immediate associates, especially the family. An adequate history, properly taken, is an important step in the treatment process. The physical studies indicated by the patient's symptoms must be thoroughly performed. They should be sufficiently comprehensive to enable the examining physician to determine the physical status of the patient but should be conducted in such a manner that the anxiety of the patient is not increased. Frequently extensive examination procedures are interpreted as evidence of serious physical disease. The steps in making a positive diagnosis of an emotional disorder or tension state should begin at the first contact with the patient and should accompany other procedures. The diagnosis of emotional factors in illness under no circumstances should be made by exclusion. Too much emphasis cannot be placed on the establishment of a satisfactory personal relationship between the physician and patient. This should be neither too friendly nor too reserved but a happy compromise, which will gain for the physician the proper degree of respect from the patient.

The patient needs to know a great deal about his own personal views and prejudices. It is difficult to understand the problems of others unless one has some understanding of one's self. The physician's emotional bias must not be allowed to influence his attitude toward the patient. Constant attempts to understand the patient's point of view are necessary, and no matter what material may come out of the interview, the examiner should neither criticize nor for that matter approve of any activity which the patient may describe which has been the source of conflict. Under no circumstances should the physician assume an attitude of superiority or should the patient get the idea that the physician does not have time to listen to the patient's story. On the other hand, it is necessary to keep the patient on the subject and to prevent him from speaking at length about matters which have no significance in regard to the patient's difficulty. Significant statements may be made without warning and should be watched for continually. Interestingly enough, patients often will preface a particularly important comment by the statement, "This isn't important and I shouldn't waste your time about it." In the treatment procedure it is important to realize that the patient may have to discuss early conflictual situations which may have become transferred to contemporary persons or to contemporary environmental situations. This may appear to be a time-consuming process but actually is less so for the patient and certainly less expensive and less traumatic than a whole series of irrelevant and unimportant physical diagnostic procedures.

When the diagnosis of an emotional disorder has been established and the physical factors are found to be unimportant or not present, or have been satisfactorily treated, the danger of having a "nothing wrong attitude" must be kept in mind. To tell a patient that he has a "nervous stomach" or "nervous exhaustion" is extremely harmful. It gives the patient a handle to which he may attach his symptoms and tends to make him persist in retaining such symptoms.

The reeducation of the patient in the principles of mental and physical health, at the same time giving him some understanding of the means by which his symptoms may occur, is of importance. Interpretation of the symptoms to the patient is of value, but care should be exercised in this regard. Seldom should more than tentative interpretations and correlations be made. An approach such as "Do you think this might be bothering you?" may lay the groundwork for adequate understanding on the part of the patient of his difficulty. Not only the patient but his family should have adequate insight. The patient must understand that he is not being accused of putting on or of imagining his difficulty. He must realize that the symptoms are just as real and as significant, if not more so, as they would be if due to some physical process. If the patient's symptoms even in part are consciously motivated, it must be realized that there is a reason for it; in this field, as in all others, there is no effect without a cause. Almost more important than having the patient understand these factors is the necessity of understanding and acceptance on the part of the patient's family. Criticism, ridicule and jests tend to increase symptoms rather than to relieve them. Such procedures should never be a part of the approach of either the physician or the family.

---

[2] Menninger, K. A.: The Abuse of Rest in Psychiatry, Bull. of the Menninger Clinic 9: 162 (Sept.) 1945.

As mentioned earlier, rest is much abused. Great harm can be done by the prescription of unneeded rest. Too much emphasis on this factor tends to convince the patient that he does have a physical basis for his symptoms, and since most of these patients would much rather blame their symptoms on a physical process such emphasis gives them just the opportunity that they constantly desire. It is more painful to face the issue but likewise far more healthful. Excellent practical recommendations for the understanding and treating of these patients is to be found in a technical bulletin issued by the United States War Department[3] and in a recent article by Rennie[4] in the *Bulletin of the New York Academy of Medicine* for January 1946.

Recognition of the importance of emotional factors in illness, a willingness to spend more time with such patients, an understanding of some of the motivating factors in such conditions and the ability to help in the solution of such problems is an essential characteristic of every good physician.

As a concluding remark, I should like to quote from that great physician, Sir William Osler. "The practice of medicine is an art, not a trade; a calling, not a business; a calling in which your heart will be exercised equally with your head. Often the best part of your work will have nothing to do with potions and powders but with the exercise of an influence of the strong upon the weak, the righteous upon the wicked, of the wise upon the foolish."

ABSTRACT OF DISCUSSION

Dr. Karl M. Bowman, San Francisco: I agree with everything Dr. Waggoner has said. I would like to bring up three additional points. First: Psychoneuroses are usually seen first by physicians from other fields of medicine than psychiatry. It is most important, therefore, that every physician have some understanding of these conditions and be prepared to deal with them. He should not dismiss such a patient by telling him that he is just imagining things and that there is nothing the matter with him. The physician should be prepared to treat the patient by reassuring him and starting him on the road to recovery. While it is not to be expected that physicians in general will become expert psychiatrists, they should have enough understanding of the subject to make a *preliminary* diagnosis and to see that the patient is referred to one from whom he can secure appropriate treatment. Second: It is important to remember that one is treating a person who is sick, and that the personality of this patient may be as important a factor in determining recovery as the sickness itself. To some persons sickness represents either a way to escape responsibilities or unpleasant tasks or a means of dominating or punishing others. It may also be a way of getting prestige or money, and every one is familiar with the difficulty in treating patients whose illness represents a financial gain. The method of examining a patient suspected of being psychoneurotic is of the greatest importance. The manner in which a physical examination is performed may either reassure and help toward cure or may terrify the patient and convince him that he has a serious disorder, thus making treatment more difficult. Third: It should be emphasized that no two persons are exactly alike and that the methods of approach, of study and of treatment that work with one patient will not work with another. This personality factor must be dealt with in all cases of sickness, whether mental or physical, and this cannot be done adequately by stereotyped methods.

Gen. Eugen I. G. Reinartz, United States Army: I should like to stress the importance of a paper such as Dr. Waggoner's to the general practitioner. There are some who do not take proper cognizance of the extremely important psychologic aspect of the patient who comes to them. The physician must think of a patient as a whole, not as one who presents certain symptoms. It has been my good fortune to have been Commandant of the School of Aviation Medicine where more than five thousand outstanding physicians have come for instruction and graduation. The courses in neuropsychiatry were the most popular of the entire curriculum. I am glad to say that this has added to the 2 per cent which Dr. Waggoner mentioned as the number of physicians psychiatrically motivated. This will be a happy leaven in the medical population of the United States as a whole.

Dr. John Z. Brown, Salt Lake City: For a number of years I have been concerned about my lack of training in this field, and I want to compliment Dr. Waggoner for calling attention to this great problem. I hope that this section will have more papers like this. When I was a student Dr. Sippy always said "Be sure to make a distinction if you can as to whether this problem is functional or anatomic." I have had as patients within the last eighteen months 6 young men with these symptoms who have come home from the government service. I think Colonel Chamberlain, who has charge of the psychiatric division at the Bushnell Military Hospital at Brigham City, Utah, is vitally interested in this problem. Dr. Waggoner appreciates the fact that so many of these questions which are dismissed as trivial really are not trivial. The number of young men who have been in the service and whom the Army is trying to rehabilitate is legion, says Colonel Chamberlain. The point I want to emphasize is that this problem is going to be met by general practitioners more frequently than it has in the past.

Dr. Raymond W. Waggoner, Ann Arbor, Mich.: The question raised by Dr. Bowman, that of the time involved in handling patients with neuropsychiatric difficulties, should be emphasized. I am much impressed with the need for taking a little more time in order to give the patient that extra understanding that may relieve him of his tension and allow him to take his place again in society without the manifestation of these symptoms. It is gratifying to know that in the early phase of a difficulty of this sort a short period of discussion by an understanding physician may relieve the patient of most of such symptoms. I cannot emphasize too much the fact that physical manifestations may frequently be the result of psychologic or emotional factors. Dr. Brown's reference to the boy who came to him and said, "Am I a nut?" raises a very important problem. Some doctors belittle a patient who has a gastrointestinal disturbance on a functional basis. These illnesses are just as real and oftentimes far more significant to the patient than a physical illness. Anyone has the possibility of developing an emotional disorder if the stress to which one is subjected in everyday life is sufficiently heavy.

Clinical Notes, Suggestions and New Instruments

DERMATITIS OCCURRING DURING THERAPY WITH TRIPELENNAMINE HYDROCHLORIDE ("PYRIBENZAMINE HYDROCHLORIDE")

ERVIN EPSTEIN, M.D.
Oakland, Calif.

It has been discovered that most of the so-called "miracle drugs" introduced during the past few decades have had the potentiality of causing cutaneous reactions. The dermatoses resulting from the therapeutic application of the trivalent arsenobenzols, penicillin, the sulfonamide compounds and dinitrophenol, have limited the usefulness of these agents. However, to date there have been no reports of dermatoses due to the antihistamine drugs, such as diphenhydramine hydrochloride ("Benadryl hydrochloride" N. N. R.) and tripelennamine hydrochloride ("pyribenzamine hydrochloride" N. N. R.).[1] Therefore the 2 following cases are reported.

REPORT OF CASES

CASE 1.—K. S., a white man aged 28, had suffered with atopic eczema since infancy. On examination on July 7, 1946 the patient presented an erythematous, pigmented, lichenified dermatitis involving the face, the neck and the flexures of the arms and legs. Treatment with diphenhydramine hydrochloride was attempted. An oral dose of 50 mg. of the drug three times a day was prescribed but was discontinued after the first day because of the patient's weakness. On September 4 tripelennamine hydrochloride was recommended in the same dosage. Within twelve hours after the ingestion of the first tablet, the patient noted the development of a smooth, erythematous, macular, oval eruption on his trunk and extremities. The dermatitis followed the lines of cleavage of the body. The distribution suggested that of pityriasis rosea. The patient was not seen until two weeks later. During this time he continued to take the drug and the condition continued to spread. On examination on September 20, the lesions were considered to represent an atypical example of pityriasis rosea. However, the medicament was discontinued and the eruption slowly subsided over a period of three weeks. On November 15 the drug was again taken. The eruption recurred eight hours after the patient consumed the first tablet. Tripelennamine therapy was immediately discontinued, and the eruption disappeared in ten days.

CASE 2.—P. H., a white man aged 42, had been afflicted with a severe form of eczema for many years. On examination he presented a dry, pigmented, lichenified, erythematous, pruritic eruption involving his ears, neck, arms and legs. Tripelennamine hydrochloride was prescribed on Nov. 29, 1946. Within ten hours after taking the first 50 mg. tablet, the patient noted a rapidly spreading, generalized, erythematopapular eruption not unlike the original eczematoid dermatitis. It was considered that this probably represented an extension of the eczema. However, the patient then offered the information that another physician had given him this drug two months before. The ingestion of one tablet had caused an immediate generalized eruption of the same type. The extension subsided in about two weeks, leaving the lesions for which the patient originally sought treatment unchanged.

COMMENT

Clinically, the 2 eruptions were dissimilar. The first mimicked pityriasis rosea, while the appearance of the second suggested an extension of the patient's eczema. However, many drugs, including the arsenobenzols, gold salts and quinacrine hydrochloride, can cause similar dermatoses. In both instances, tripelennamine hydrochloride was incriminated by the following criteria: development of the lesions while the patient was taking the compound, reasonably quick clearing with discontinuance of the drug and immediate recurrence on its readministration.

In both instances the presenting dermatitis was atopic eczema. However, a series of 2 cases is insufficient to support speculation as to the relationship of dermatitis due to this drug with atopic eczema. The fact that its use may cause an eczematoid eruption in susceptible persons is of interest in view of the theory which links eczematoid eruptions with the release of histamine.

SUMMARY

Eruptions developed in 2 patients with atopic eczema while they were taking tripelennamine hydrochloride ("pyribenzamine hydrochloride" N. N. R.). One eruption was of the eczematoid type, the other resembled pityriasis rosea. Both cleared with discontinuance of the drug and recurred on its readministration.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, *Secretary.*

EMERSON RESUSCITATOR, MILITARY MODEL, ACCEPTABLE

Manufacturer: J. H. Emerson Company, 22 Cottage Park Avenue, Cambridge, Mass.

The Emerson Resuscitator, Military Model, is designed to furnish mechanical artificial respiration to victims of asphyxia. It is operated by compressed air. A foot pump compresses the air. The resuscitator can also be operated by compressed oxygen.

The apparatus is housed in a sturdy fiberboard carrying case measuring 24 by 16 by 6 inches (60.9 by 40.6 by 15.2 cm.) which, with its contents, weighs 36 pounds (16.3 Kg.).

The air compressor is a compact unit made of heavy enameled sheet metal measuring 18½ by 5½ by 5 inches (47.0 by 14.0 by 12.7 cm.) and weighing 10 pounds (4.53 Kg.). The air pump, which has a bore of 3 inches (7.6 cm.), a stroke of 5½ inches (14 cm.) and a volume of approximately 500 cc. for each stroke, is attached to the flat hollow base, which functions as the storage tank for compressed air. When not in use the foot pedal folds compactly over the pump. At the end of the base opposite the pivot of the pedal two valve outlets with a gage for attaching the mechanism of the resuscitator are provided.

The mechanism of the resuscitator is encased in an enameled sheet metal cylinder 4 inches (10.2 cm.) in diameter and 2¾ inches tall (7.0 cm.) and weighs about 2 pounds (0.9 Kg.).

Two types of equipment are available. One model is a resuscitator only; the other has an additional valve which converts it into an inhalator. A transparent plastic face mask with an inflatable rubber cuff is attached directly to the mechanism of the resuscitator. A fabric-reinforced rubber tube 4½ feet (114.3 cm.) long connects the apparatus to the source of compressed gas.

The working parts are similar to those of the hospital model of the Emerson Resuscitator, which is accepted by the Council and is described in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, May 30, 1942, page 44. The positive and negative pressure is created by the compressed gas acting on the valve mechanism of the resuscitator. According to the manufacturer the positive cycle has a pressure of + 14 mm. and the negative cycle a pressure of — 9 mm. of mercury in the face piece. The investigation of the Council substantiated these values to an accuracy of 2 to 3 mm. of mercury. Fluids and mucus may be removed from the respiratory passages with a large rubber catheter inserted into the trachea or pharynx. Suction is obtained by a venturi valve, which is connected with one of the outlets of the air chamber of the compressor pump through an aspirator bottle.

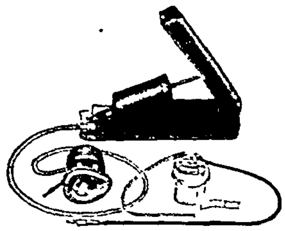
In this type of apparatus the respiratory rate is dependent on two factors: (1) the volume of gas which is necessary to create an intrapulmonary pressure sufficient to trip the valve and thereby initiate the negative phase and (2) the rate at which the gas flows into the respiratory system. The former is determined by the capacity of the lungs and air passages and is subject to individual anatomic variation. The latter is fixed at the factory by adjustments in the mechanism and cannot be changed by the operator. The respiratory rates obtained with this device are therefore determined by the capacity of the thorax of the individual on whom it is used.

When a rubber bag of 1,600 cc. was used to test the resuscitators a rate of 5 cycles per minute for apparatus under test was obtained and 8 cycles per minute in the other, while the resuscitator-inhalator operated at the rate of 10 cycles per minute. By reducing the capacity of the bag to 500 cc. the rates were increased to 10, 16 and 24 per minute respectively. The high rate of the resuscitator-inhalator was accompanied with low pressures within the bag and was due to an irregular fluttering of the valve mechanism.

When the resuscitator is operated by the foot pump, from 15 to 25 strokes per minute are required. The resuscitator-inhalator requires 40 to 45 strokes per minute. Both resuscitators can be operated, that is, two patients treated, simultaneously. This requires 35 to 40 strokes of the pump per minute, while operation of the resuscitator-inhalator and a resuscitator requires 60 strokes per minute.

With the pressure in the air chamber of the pump at an optimum for continuous operation of the resuscitator, approximately 70 foot pounds of work is needed to complete one stroke of the pump in slightly less than three seconds. At this rate 42,000 foot pounds is required to operate the resuscitator for thirty minutes.

Seven men in average physical condition operated the pump, with one resuscitator attached, for periods ranging from twenty to forty-five minutes. None were unduly fatigued, and each felt that he could have continued the work for a considerably longer period. One man was able to maintain adequate pressure to operate two resuscitators for thirty minutes without excessive fatigue. The pump was operated from a kneeling position, with both hands on the free end of the foot pedal, which allows the maximum use of the body weight and requires a minimum of muscular effort.



Emerson Resuscitator, Military Model.

Effective resuscitation using the foot pump requires two operators: one to maintain air pressure in the system and another to keep the face piece in close contact with the face to prevent escape of air, which interferes materially with the proper functioning of the resuscitator. The weight of the resuscitator mechanism (2 pounds or 907 Gm.) renders strapping to the face impracticable.

The resuscitator under investigation operated in the manner described when compressed oxygen is used. This combination can be used in operating room emergencies when the patient is in a supine position and there are no contraindications to the use of a positive pressure device.

If the apparatus is in readiness, resuscitation can be instituted within a few seconds by a person trained to use it. Clinical evidence of the efficacy and safety of this apparatus has been submitted by the firm.

The Council accepts resuscitators when critical evidence is received. The J. H. Emerson Company has submitted satisfactory information to substantiate the efficacy of this device when used in operating rooms and in medical institutions. Evidence has not been received indicating that the Emerson Resuscitator, Military Model, has been successfully employed by military personnel, firemen, policemen or rescue teams. The acceptance for the resuscitator in question is limited to its use in operating rooms and in medical institutions.

The Council on Physical Medicine voted to adopt the Emerson Resuscitator, Military Model, for inclusion in its list of accepted devices for use by physicians and adequately trained personnel who are familiar with the proper procedures to be followed in resuscitation as well as with the limitations and hazards of positive pressure, provided the advertising and descriptive matter contain the aforementioned limitations for its uses.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

PENICILLIN (See New and Nonofficial Remedies, 1946, p. 212).

The following dosage forms have been accepted:

BRISTOL LABORATORIES, INC., NEW YORK

Crystalline Penicillin Sodium: 20 cc. vials containing 100,000 units, 200,000 units or 500,000 units and in combination packages containing a vial of penicillin sodium and a 20 cc. vial of isotonic salt solution.

MERCK & CO., INC., RAHWAY, N. J.

Crystalline Sodium Penicillin-G: 100,000 unit, 200,000 unit and 500,000 unit vials.

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Crystalline Sodium Penicillin-G: 20 cc. vials containing 100,000 units or 200,000 units.

E. R. SQUIBB & SONS, NEW YORK

Crystalline Sodium Penicillin-G with Buffer: 100,000 unit and 200,000 unit vials. Buffered with sodium citrate.

WYETH INCORPORATED, PHILADELPHIA

Penicillin Sodium: 200,000 unit and 500,000 unit vials.

CONTRACEPTIVE CAPSULES AND SUPPOSITORIES (See New and Nonofficial Remedies, 1946, p. 359).

The following article now stands accepted:

EATON LABORATORIES, NORWICH, N. J.

Lorophyn Vaginal Suppositories: Suppositories consist of a low melting mass prepared from the formula:

Phenylmercuric acetate	0.05%
Glyceryl mono-laurate	10.00%
Tween 61 (Sorbitan monostearate-hydroxy polyoxyethylene ether)	89.95%

Actions and Uses.—See article Contraceptive Capsules and Suppositories.

Dosage.—One suppository containing 2.85 Gm.

ESTROGENIC SUBSTANCES (See New and Nonofficial Remedies, 1946, p. 443).

The following dosage forms have been accepted:

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Tablets Estromone: 1,000 international units, 2,000 international units and 4,000 international units.

Solution Estromone (in Oil): 1 cc. ampuls and 10 cc. and 25 cc. vials. Each cubic centimeter contains 2,000 international units, 5,000 international units, 10,000 international units or 20,000 international units of estrogenic substances in sesame oil. The 10 cc. and 25 cc. vials contain 0.5 per cent chlorobutanol as preservative.

U. S. trademark 345,724.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1946, p. 618).

The following dosage forms have been accepted:

E. S. MILLER LABORATORIES, INC., LOS ANGELES

Solution Thiamine Hydrochloride 10 mg. per cc.: 1 cc. ampuls.

Solution Thiamine Hydrochloride 50 mg. per cc.: 1 cc. ampuls.

BACTERIAL VACCINE MADE FROM PLAGUE BACILLI (See New and Nonofficial Remedies, 1946, p. 577).

The following dosage form has been accepted:

CUTTER LABORATORIES, BERKELEY, CALIF.

Plague Vaccine: 20 cc. vials containing 2,000 million killed bacilli.

SATURDAY, JUNE 28, 1947

POLIOMYELITIS VIRUS IN NERVOUS TISSUE

Bodian and Cumberland[1] report a study of the changes of virus titer in infected nervous tissue in all stages of the disease. The Lansing strain of poliomyelitis virus was used to permit an adequate titration of virus samples in mice. The virus levels in the spinal cord throughout the course of infection were studied in rhesus monkeys inoculated intracerebrally with Lansing virus, although another strain, avirulent in mice, was used for comparison of the time of persistence of virus in the recovery period. Spinal cord enlargements, including segments from the fifth cervical to the first thoracic and the fourth lumbar to the first sacral inclusive, were removed and split into right and left halves. Each half was then split into dorsal and ventral halves. Thus the cord suspensions prepared from the ventral quadrants contained all the neurons responsible for the muscle function of each limb. Virus levels were studied in the ventral quadrants of the cervical and lumbar enlargements of the spinal cord separately, so that correlation with the degree of paralysis could be made if possible. The authors made use of an unusual feature of the disease in monkeys, which is the initial paralysis of the arms in 75 per cent of cases followed by leg paralysis in the course of about twenty-four hours. This lag in leg paralysis is paralleled by a later onset of virus proliferation in the lumbar cord as compared with the cervical cord.

Intracerebral inoculation in monkeys is followed by a latent period of an average duration of seven days. During this period lesions or proliferated virus cannot be detected in the central nervous system. Signs of an active disease process begin with an early preparalytic period lasting about one day and characterized by early lesions in the brain which extend down the brain stem to the level of the upper spinal cord. Fever may or may not develop during this period. Virus cannot be detected in arm or leg segments of the cord as yet. A prodromal, late preparalytic period with an average duration of about one day follows and is characterized by increase of intensity of cerebral lesions and by consequent clinical signs of fever, generalized muscle spasticity and tremor. Lesions and high concentrations of virus are now found in the arm segments of the spinal cord, but virus and lesions may or may not become apparent in the lumbar cord at this stage. This sequence of events, according to the authors, is characteristic of Lansing virus infection in monkeys.

The authors expected to find a correlation between severity of paralysis and heights of virus titer. They found, however, that peak concentrations of virus could be reached within one day of the onset of the pathologic process and before clinically evident paralysis occurred. At this time, although some cells are really destroyed by virus action, most affected cells are apparently in various stages of chromatolysis. Probably peak concentrations of virus are achieved in such cells before their function is lost. By the time paralysis first appears, many motoneurons are severely injured or destroyed, neuronophagia is common and maximal concentrations of virus may still be obtained. The appearance of much neuronophagia at a time when high concentrations of virus occur suggested that the infectivity of the tissue is directly proportional to the amount of neuronophagia. This proportionality is incidental and is not directly related to the dynamics of virus multiplication and is true only in the earliest stages of the pathologic process. Soon thereafter the virus titer may drop precipitately, but neuronophagia may still be present in considerable amount and paralysis may even increase as injured cells continue to die.

These studies then reveal that peak concentrations of virus are achieved within one day after the virus is first demonstrated, and maximal concentrations are maintained for an average period of two days. These two days are the day preceding paralysis of the limb corresponding to spinal cord segment and the first day of paralysis. A sharp dampening effect on virus multiplication occurs on about the second day of paralysis. On the third day most cord segments have virus concentrations below the mouse infectivity threshold. Virus, however, can subsequently be detected for at least two weeks by subinoculation in rhesus monkeys. Since peak concentrations of virus may occur during the early stages of pathologic change, before sufficient motoneurons are destroyed or so injured that clinically evident paralysis occurs, and since virus levels decrease after the first day of paralysis, correlations of virus titer and severity of paralysis cannot be adequately made. The stage of the disease during which a sample of virus was obtained appeared to be without influence on the incubation period in animals inoculated with that sample.

These studies throw considerable light on the dynamics of poliomyelitis infection and likewise contain implications with regard to the possibilities of chemoprophylaxis and chemotherapy.

THE SUPPLY OF DOCTORS

Recently a national periodical—*Collier's*—published a misleading article by Albert Maisel entitled "So You Can't Get a Doctor!" This long and somewhat confused statement purports to demonstrate that there is an acute shortage of doctors in this country and that deans of medical schools are callous to this alleged need, as shown by termination of the accelerated program in most schools and the reduction in freshmen enrolments to prewar levels.

Much of the material in this article is sheer nonsense. The author begins with a partial quotation from a publication of the American Medical Association, taken out of its context, predicting a postwar shortage of doctors. Actually this estimate was made when the end of the war seemed far distant and the military authorities were refusing to allow able bodied men to enter premedical studies. The figures quoted were based on military estimates of the physician need for a large peacetime army and navy, universal military training and a staff for the Veterans Administration three times the number now actually employed. Only a fraction of the anticipated number of physicians is now employed in these services.

While contending that maldistribution of doctors is not the major factor in the alleged shortage, Maisel selects as outstanding examples of shortages two states with per capita incomes well below the national average, and—of all places—Kelley's Island, 4 miles out in Lake Erie! The evidence for shortages even in large cities is based on replies to telegrams asking whether there exists in large cities a "surplus of physicians available for transfer elsewhere . . ." No wonder negative replies were received from fifteen cities. Even where a surplus might exist, physicians are not "available for transfer" to a place to which they do not choose to go any more than are engineers or day laborers.

Whether or not there is a real shortage of doctors requires a far more careful study than the mere sending of a few telegrams. Such studies are under way in several states, and in the country at large. The population of physicians in this country has increased somewhat more rapidly than the population at large in the past twenty years. Whether or not there is a real total shortage, some maldistribution prevails and redistribution is extremely difficult in a democracy. Men are free to work in a place where there are facilities for good work, such as hospitals and diagnostic equipment, stimulating professional and educational contacts and reasonably good family living conditions, and where a reasonably good income is possible.

There is close correlation between the per capita income of states or counties and the numbers of physicians who locate in any area. Such location is insignificantly affected by establishing more medical schools, increasing enrolments or accelerating the curriculum. More promising are the efforts now being made: the provision of hospital and diagnostic facilities under the Hospital Survey and Construction Act, the extension of prepaid medical care insurance, the strengthening of the status of the general practitioner, the information service on areas needing physicians, the intimate liaison of organized medicine with farm organizations, and similar considerations.

The reason for the cessation of acceleration and the return to prewar enrolment numbers is simple: medical educators were not doing as good a job of training physicians during the war as is now desired. More than 7,000 extra doctors were produced during the war. This was necessary. In many schools, facilities and strength of faculty now do not warrant maintenance of large enrolments or an accelerated program, without a serious sacrifice of high quality. Numbers can never replace quality, especially in medicine. On these questions there is virtually unanimous agreement among medical educators, deans, faculty members, the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association.

BIOGENESIS OF THE STEROIDS

In the animal the steroids are important. The bile acids, the estrogens, the androgens, the adrenal cortical hormones, the cardiac glycosides, cholesterol and the 17 ketosteroids are all lipids. These substances are intimately interrelated, differing primarily in the type and position of their nuclear substituents. After the isolation of cholesterol by Poulletier in 1769 the origin of this substance and its possible position as the precursor of these alicyclic compounds invoked much investigation.

The endogenous nature of cholesterol was demonstrated in 1925.[1] These results were confirmed;[2] further it was shown that plant sterols, by virtue of their nonabsorbability, do not contribute toward synthesis of cholesterol. Many controversial claims have been made relative to the site of cholesterol formation, with the spleen, adrenals, liver and gonads occupying predominant positions; nevertheless the site of formation of cholesterol is still unknown.

Many studies have been made on the possible precursors of this steroid, and several suggested precursors such as oleic acid, squalene and carbohydrates have been considered. Recently it has been conclusively shown[3] that cholesterol is synthesized in the animal from small molecules such as water and acetic acid.

The predominant question in the biogenesis of the steroids is whether cholesterol serves as the parent compound or whether these substances are synthesized de novo. It has been suggested[4] that cholesterol, after oxidative degradation, serves as the precursor to the steroid sex hormones. In 1943 the in vivo conversion of cholesterol to cholic acid was demonstrated.[5] The following year the transformation of desoxycorticosterone to pregnandiol was shown.[6] Further interrelationships among the steroids become evident when the cortical activity of progesterone and the progestational response to the alkyl testosterones were considered. The work[7] of the cholesterol content of the adrenal during hemorrhagic shock and on administration of the adrenocorticotropic factor of the pituitary presents additional indirect evidence of the biologic conversion of cholesterol to other steroids. The administration of labeled cholesterol to a pregnant woman and its subsequent conversion to pregnandiol[8] prove conclusively that the former occupies a key position in the biogenesis of some of the steroids. Much additional research is required in allocating the exact position of cholesterol in the biologic synthesis of the various steroids in the mammalian organism.

Current Comment

CONSERVATIVE APPROACH TO VAGOTOMY

Acting on the concept that the hypersecretion of gastric juice in gastroduodenal ulcer is largely neurogenic, Dragstedt treated a series of patients who were troubled with more or less intractable gastroduodenal ulceration by utilizing an operation designed to remove permanently and as completely as possible the vagus innervation of the stomach. Grimson, Moore and others have reported favorable results from this operation. Lahey[1] now issues a warning against too enthusiastic reception of an operation which has not stood the test of sufficient observation. Gastroenterostomy for gastric or duodenal ulceration was accepted at one time as the operation of choice but fell into disrepute because of the high incidence of postoperative marginal jejunal ulcer and gastrojejunocolic fistula. Moreover, the operation, when not followed by these formidable complications, did not protect the patient against recurrence, hemorrhage, perforation or malignant degeneration of the gastric ulcer. Admitting that vagotomy will decrease or abolish gastric acidity and decrease hypersecretion and hypermotility, Lahey objects to its routine employment because of the frequency with which gastroenterostomy is required as part of the procedure. There is no adequate proof that gastric acidity may not return and that therefore there may not be a continuation of the recurrence of gastrojejunal ulcers and gastrojejunocolic fistulas as a result of these gastroenterostomies. While immediate relief of pain and ability to eat anything have been reported following vagotomy in many cases ulcers have recurred in some; there have been cases of cardiac arrest and fatalities probably associated with a hypersensitive vagus and a vagovagal reflex; there have been patients with abdominal distention, and there have been technical complications following the employment of this operative procedure. Vagotomy in Lahey's opinion would be ideal for a patient who had had a subtotal gastrectomy and then had a recurrent jejunal ulcer. Even though atony in the remaining stump is produced, there is still good drainage and there is no contracted pylorus to produce obstruction. In the Lahey Clinic infradiaphragmatic vagotomy is now employed for most of the patients on whom subtotal gastrectomy is done for duodenal ulcer. Because subtotal gastrectomy has had a low mortality, it is still preferred to any other intervention for the treatment of gastroduodenal ulceration. Since 1937 the mortality of subtotal gastrectomy for duodenal ulcer in the Lahey Clinic has amounted to 2.1 per cent, for gastric ulcer 0 and for jejunal ulcer 1.9 per cent. A conservative approach to vagotomy is advocated principally on the ground that sufficient time has not elapsed to evaluate both advantages and disadvantages of the procedure. Likewise the comment appeared in THE JOURNAL that the period of observation has been too short to permit a final evaluation of the method and that the question of ultimate regeneration of the divided vagi remains undecided.[2] Such complications as dilatation of the stomach and greatly impaired motility make necessary delay in final conclusions regarding the exact value of the procedure.

BRUCELLOSIS IN THE UNITED STATES

Approximately 4,000 cases of human brucellosis are reported annually to the state departments of health, but projection of the results of detailed local studies indicates that there are at least 30,000 to 40,000 actual cases. Alice Evans,[1] one of the pioneers in the study of brucellosis in this country, emphasized the discrepancy between the number of cases reported annually and the probable number of existing cases. A method of laboratory or clinical diagnosis is needed that will reveal the milder forms of the disease. Also desirable are methods for the control of brucellosis in animals and an effective therapeutic agent. The problem of diagnosis is particularly well illustrated by her own experience. Dr. Evans became infected in 1922 while working on cultures of Brucella melitensis. At first the disease was mild. For five years poor health repeatedly diagnosed as "neurasthenia" continued. Only accidentally during surgical intervention for another disease were brucellar lesions found from which B. melitensis was cultivated. The development of better methods of control, diagnosis and treatment of this widespread disease is one of the most pressing unsolved problems facing the medical profession.

ORGANIZATION SECTION

PROCEEDINGS of the ATLANTIC CITY SESSION

MINUTES OF THE ANNUAL SESSION OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, HELD IN ATLANTIC CITY, JUNE 9-13, 1947

(Continued from page 717)

HOUSE OF DELEGATES

Second Meeting—Tuesday Morning, June 10

The House of Delegates was called to order at 9:20 a. m. by the Speaker, Dr. R. W. Fouts.

Roll Call

On motion of Dr. Arthur J. Bedell, Section in Ophthalmology, seconded by Dr. Thomas S. Cullen, Maryland, and carried, the House directed that the signed registration slips constitute the roll call.

Presentation of Minutes

It was moved by Dr. H. B. Everett, Tennessee, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried, that the House dispense with the reading of the minutes.

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, chairman, announced that 173 delegates had been registered.

Report of Committee to Study Revision of the Constitution and By-Laws

The Speaker announced that the time had come for the House to consider the report of the Committee to Study Revision of the Constitution and By-Laws, and stated that Dr. F. F. Borzell, Chairman of that committee would read the proposed new By-Laws paragraph by paragraph and the members of the House would be given an opportunity to amend or to change each paragraph at the close of its reading.

Dr. Borzell read the proposed By-Law referring to membership and called for amendments. Dr. Allen H. Bunce, Georgia, called attention to the fact that part of this was contrary to the present Constitution by which the Association must be governed at least until next year.

After further discussion, it was moved by Dr. James C. Sargent, Wisconsin, seconded by Dr. H. B. Everett, Tennessee, and carried after discussion by several that consideration of the proposed revised By-Laws lie over a year until the proposed revised Constitution can be considered.

Presentation of Invited Foreign Guests

Dr. Morris Fishbein, Editor of THE JOURNAL, introduced Dr. Hugh Clegg, Editor of the *British Medical Journal;* Dr. Charles Hill, Secretary of the British Medical Association; Dr. J. A. Pridham, Chairman of the Committee on International Relations of the British Medical Association, and Dr. Guy Dain, Chairman of the Council of the British Medical Association. Dr. Dain addressed the House as follows:

Gentlemen, it gives me very great pleasure to be able to come to you and bring to you the message of good will from my Association. We are, shall we say, brother associations. The difference in our ages is not so enormous but what we are an elder brother for you. We had our centenary fifteen years ago. I would first say that we wish you very many happy returns and a very happy birthday this year in Atlantic City.

We thank you very much for the invitation which was issued to our Association to send representatives to be present at this great gathering. In coming, I want to take a moment to congratulate the American Medical Association on its achievements in its first hundred years. Obviously, I can't go over all its achievements, but I do want to single out three as being to my mind outstanding for a reason I will give you.

If you compare medical education in your country with what it was a hundred years ago and look at what your Association has done to raise the standard of medical education and qualification for the whole of the states, I think you can be extremely proud of that achievement.

Again, the work which you have done on the "patent" medicine question has been of outstanding value to the public in setting up new and more proper standards in the sale of drugs.

Then, in the third place, there is your own JOURNAL. I don't know whether Dr. Fishbein will be very pleased if I put it third in the order in which I have referred to things, but the standard of THE JOURNAL has had an enormous effect on the standards of medicine in the United States.

What I want to say to you is that it appears to me that the lesson we at home as well as you here want to learn from it is what may be accomplished by high purpose and courage. You have achieved these things without any of what we call at home "statutory powers"; you have had no government department behind you to see that the things you set out to do were accomplished. You have done it by educating your medical public and your general public to a higher standard in the matters which concern their well-being. For that you should have the very highest praise. For that to be done by a voluntary body without any statutory powers is an enormous achievement.

A person who reaches his hundredth birthday is concerned entirely with looking backward. You, as an organization, must look forward. I won't attempt to prophesy the great work you will accomplish in the next hundred years. I do want to say this one thing, that we on the other side of the Atlantic are very delighted that you have decided to take a hand in the establishment of the World Medical Association.

Coming to a birthday party, it occurred to us that it was quite an ordinary thing to bring a birthday present, and we were under considerable difficulty to decide what sort of present can possibly be given to an organization a hundred years old that it would not already have bought or have given to it. While I have no doubt that you have perhaps one or more, several, of the gadgets which I propose to offer to the Association from the British Medical Association, you won't have one which can convey better will than the one I offer you today, and that is a gavel and block for the chairman's use.

In order that it may tie the two countries perhaps a little closer together, I may tell you that it is made from the wood of the mulberry tree which stood in Charles Dickens's garden at Tavistock House when he was living there between 1851 and 1860 and writing books such as "Little Dorrit" and "Great Expectations." When we took over the property on which the British Medical Association House is built, that mulberry tree was standing there, and unfortunately it had to be taken down.

We offer you a bit of the wood with an inscription from the Association as a token of our good will and our good wishes for the next hundred years.

Dr. Fishbein requested Dr. R. L. Sensenich, Chairman of the Board of Trustees, to receive the gift, but in Dr. Sensenich's absence, Dr. George F. Lull received it with the following remarks:

Dr. Dain and Gentlemen from the British Medical Association:

It gives me great pleasure to appear for the Chairman of the Board of Trustees to accept this gift. The inscription reads as follows:

"To the American Medical Association on the occasion of its centenary, as a token of good will from the British Medical Association, this gavel and block made from the mulberry tree which grew in the garden of Charles Dickens's home in London, where the British Medical Association House now stands. June 1947."

I can assure you, on behalf of the House of Delegates of the Association, that it will be treasured and, coming from the British Medical Association and its home in London, it will be doubly appreciated. Thank you.

Dr. Fishbein then presented Dr. Sigurdur Sigurdsson, Chief Medical Officer of Tuberculosis Control and representative of the government of Iceland and the Icelandic Medical Association, who spoke as follows:

Mr. Chairman, Members of the House of Delegates:

I have a special honor in being able to be present at your meeting. I come a far way from one of the smallest and oldest democracies of the world, from Iceland, which has only as many inhabitants in thousands as the United States has inhabitants in millions. But in spite of that we are rather a small nation we try to keep our independence and special culture, which is one of the oldest in Europe.

We have our own university and the biggest faculty of that is the faculty of medicine. We have managed to keep the health standard in Iceland as high as that of the best nations; for instance infant mortality in Iceland has for many years been one of the lowest in the world and some years it has been lower than in any other country.

I myself am leading the antituberculosis campaign in our country, and this disease was a great problem there. In 1930 we lost 21.6 per 10,000 of the population through that disease. Through organization of the antituberculosis work and especially through mass x-ray examinations of the people, which now comprise about 60 per cent of the whole nation, we have in fifteen years succeeded in reducing the tuberculosis mortality from 21.6 to 6.8 per 10,000 population, that is 68.5 per cent. As far as I know, the capital of Iceland is the only capital in the world where almost every individual has been given x-ray service, and the Icelandic nation the only nation where 40.8 per cent of the whole population has been x-ray examined in only one year.

Iceland and America have from the first been strangely related, as first discovery of this country was by a young Icelander, born and bred there, whom you might have heard of, Leif Ericson.

In the last war there has again been considerable cooperation between my small nation and your great nation. Also there have been very pleasant relations between American doctors and American medical science and my country. Therefore, it is a great pleasure to me, in the name of the Icelandic government and of the Icelandic Medical Association, to express my thanks to the American medical profession and to wish the American Medical Association good luck and great progress in its noble service to humanity.

I thank you.

Dr. Fishbein then introduced Dr. F. Kingsley Norris, representing the British Medical Association in Australia, who addressed the House, as follows:

Mr. Speaker, Ladies and Gentlemen:

I come probably farther than most people here, about 15,000 miles, but it is a great privilege to come to you here and, on behalf of the British Medical Association in Australia, to wish you well and to thank you for all the great things that you have done. But to us, apart from those great things, you have done many other things. Your Rockefeller Foundation and your Carnegie Endowment have made it possible for many of us to come abroad and to be with you and see the great things that you have done. I will just give you one personal incident of what you people have done for me.

It was my privilege to be in charge of the medical units in New Guinea, where there were a number of American units. At one time our supplies were very short. We had no means of supply except dropping, and we were running desperately low and short of anesthetics Near me was an American unit, and along to me came the commander of that American unit. He said "I believe you are running short of anesthetics. I don't know anything about this lease-lend business, but anything we have is yours." I won't give you his name because that was not an individual speaking. That, I believe, was the whole American nation.

That was the spirit in which we served, and that was the spirit in which we lived. For those things and for that sentiment we are deeply indebted to you.

If you will allow me, I will just close with a quotation from one of your own medical men, Oliver Wendell Holmes. I may not quote it correctly. You may know it better than I do, but he was referring to a hundred years, and I think he said "Little of all we value here reaches the morn of its hundredth year without both looking and feeling queer. There is little I know that retains its youth except, as far as I know, a tree and a truth." That is broadly a quotation from one of your own medical men, Oliver Wendell Holmes.

Now you have reached the morn of your hundredth year without both feeling and looking queer, and you have retained your youth because you have built on those two things: soundness and truth.

For what you have done and for the privilege of allowing me to come here today, to meet you and to be with you, on behalf of the Australian Branch of the British Medical Association, we wish you well and thank you sincerely for the very greatest gift, that you have given always to the world.

Dr. Fishbein then presented Dr. Einar Geert-Jørgensen, senior physician of the Municipal Hospital of Copenhagen, chairman of the Danish Neurological Society and representative of the Danish Medical Association at the One Hundredth Anniversary of the American Medical Association, who addressed the House, as follows:

Mr. President, Ladies and Gentlemen:

As a delegate from the Danish Medical Association, I have the great honor to thank the American Medical Association for the invitation to the solemn Centennial Celebration of this most distinguished society. You must understand that it is impossible for me, as it would be for every Dane, to attend this session without thinking of our American colleagues who served in the war and who did their important and dangerous work. But especially I must think of the many of these brave and unselfish colleagues who lost life and health and I can, and must, say that we Danes never will forget what we owe our American colleagues and what we owe the United States of America who gave us back our lost and beloved freedom.

The German occupation was a dreadful time for us, and we will always remember and never forget the 5th of May 1945, the sunny day when the Allied troops came to Denmark, the day of freedom, peace and relief for our little nation, which loves freedom and peace as much as the great American nation does.

In the name of the Danish Medical Association but also in the name of all Danes, I request you to receive our best and most respectful thanks.

Then it is my pleasant duty to congratulate the American Medical Association and to bring our kindest regards and best wishes for the future of your famous society.

It is important to me to express our admiration for the great work that until today has been done by the American Medical Association for the progress of science and medical experience and thereby for the health of the American nation and the whole world.

At last it gives me great pleasure to deliver you a gift from the Danish Medical Association. It is an old book, Acta Medica

Bartholini, the first medical paper in Denmark, edited by our famous scientist and physician Thomas Bartholini, who lived in the late middle ages. At that time and in the next two hundred or three hundred years, progress in the sciences came from Europe, but in the last two to three decades, progress in science and especially progress in medical science has come from the United States of America.

This book is the first edition and I hope that you will appreciate it as much as we do.

With these few and I am afraid poor words which not sufficiently have explained our feelings for you and for the work you have done in the past years, I wish you—members of the powerful American Medical Association—a future with peace and friendship with other nations and a future with tenacious and incessant fighting against our common enemies, disease and ignorance.

Dr. Fishbein then introduced the representative from the government of Syria, Dr. Chafic Trefi, who spoke as follows:

Mr. Chairman, Ladies and Gentlemen:

The people of the republic of Syria, who have always had the warmest regard for the democratic people of the United States, are happy to cooperate internationally, not only to attain security, but also to improve health, because we believe sincerely that without a high standard of health throughout the world it is impossible to have harmonious international relations.

It is in this spirit and with this privilege that I come among you, bringing the sincere salute of our sanitary authorities, and celebrate with you the Centennial of the American Medical Association, which contributes enormously to the progress of medical science in all its domain.

The republic of Syria, because of her geographic position in the eastern Mediterranean, forming a bridge between the East and the West, has always shown a great interest in medical affairs. It was for this reason that, when our government became free and independent, it created a Ministry of Public Health.

It has also undertaken an extensive new health program, aiming to increase the number of doctors, hospitals and dispensaries. Actually there is no area in Syria without public health service or sanitation facilities, aiming to health security for all, regardless of residence, creed, religion or race.

A field survey of the country was carried out in order to evaluate the particular needs of individuals, because we believe that the only sound foundation for the best health service from every aspect is that of prevention. The Department of Health in Syria has the responsibility of administering a program providing maternal and child health service, medical, hospital, nursing and dental care for the indigent and medically indigent of the country.

At Damascus, our capital, we have five state hospitals with 2,000 beds, not counting the private clinics and university hospitals which are independent of the Ministry of Public Health. At Aleppo, where I work, we have four state hospitals with 1,500 beds, and in every Syrian town there is at least one state hospital and two or three dispensaries. The Syrian government in its new plan considers having a dispensary or a nursery in every Syrian village. In addition to these hospitals, there are also obstetric hospitals, sanitariums, sanitary inspectors and mobile units, with doctors and nurses to undertake both preventive and curative medicine, who will be continually traversing the country.

There are also modern laboratories to prepare vaccines against smallpox, typhoid and tetanus, and laboratories, both fixed and mobile, for the examination of drinking water. In all our state hospitals and dispensaries all treatment is free. The whole health service, including doctors and hospitals, is paid for by the state. The hospitals are provided with all the more modern adjuncts as regards x-ray, instruments and drugs such as penicillin.

The government has not limited itself to the health problem in its own country but has sent medical missions into other countries, and I myself have the honor to be a member of the mission that has been sent to the United States not only with the object of making ourselves acquainted with the progress of general medicine in this great and generous country but also to orient ourselves in various specialties such as surgery, microbiology, pediatrics, psychiatry and x-ray.

It is in this way that you, Ladies and Gentlemen, may believe that we will always be sincerely happy to work with you in a spirit of cooperation for the good of humanity, and in the name of the Syrian government I am pleased to greet you on this eventful occasion and to wish you continual activity and success in the service of your country and the world.

Dr. Fishbein acknowledged, on behalf of the American Medical Association, the priceless gift presented to the Association by Dr. Jørgensen, which will be available for exhibition in the headquarters office whenever the delegates may come to see it. He added that additional delegates and invited guests from other countries would be presented at the 2 o'clock meeting.

He introduced Dr. Augosto F. Conde, representative of the Cuban Association of Physicians, and Dr. Felix Hurtado, Dr. José Angel Bustamente, Dr. Gustavo Aldereguía and Dr. Guillermo G. Lopez, also of Cuba, Dr. Hernante Corhata of Venezuela, Dr. Francisco J. Aguilar, representative of the Medical Federation of Guatemala, and Dr. T. C. Routley, representing the Canadian Medical Association and the World Medical Association.

Dr. Routley addressed the House, as follows:

Mr. Speaker, Mr. President, Distinguished Guests and Members of the House of Delegates:

As many of you are aware, it has been my privilege each year for the past twenty-four years to bring you a message of good will from the Canadian Medical Association. On this, your centenary, I am very happy indeed once more to be the ambassador from the medical profession of the Dominion of Canada, not only to convey our good wishes and congratulations but also to express the hope that your second hundred years may be as highly successful and satisfactory as your first hundred years have been.

It is also my delightful privilege to bring you greetings from the World Medical Association, the baby member of the family of medical associations but one which is designed to play a very significant part in the promotion of health and better understanding among people of good will throughout the world.

In September 1946, on the invitation of our medical colleagues in France and Great Britain, an International Medical Conference was held in London for the purpose of considering the organization of a worldwide medical body. Delegates and observers from thirty-two national medical associations, including your own Association, met together for several days, on the conclusion of which it was unanimously agreed to organize a World Medical Association with the following objects:

1. To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available.
2. To maintain the honor and protect the interests of the medical profession.
3. To study and report on the professional problems which confront the medical profession in the different countries.
4. To organize an exchange of information on matters of interest to the medical profession.
5. To establish relations with, and to present the views of the medical profession to the World Health Organizaiton, UNESCO and other appropriate bodies.
6. To assist all peoples of the world to attain the highest possible level of health.

An Organization Committee of thirteen members was appointed, including Dr. L. H. Bauer and Dr. E. L. Henderson from your own Association. The committee has met three times, and arrangements are nearing completion for the World Medical Association to hold its first meeting in Paris, France, during the week of Sept. 15, 1947. Already eighteen medical associations, including all of the larger ones, have signified their desire to become members of this new body. Your committee believes that, in the not too distant future, every national medical association of any importance throughout the world will enjoy membership in the World Medical Association.

It is not the purpose or intention of the World Medical Association to intrude into those affairs which constitutionally belong to individual associations and countries. The World Medical Association is not a super body, desiring to dictate to any one. On the contrary, the World Medical Association conceives it to be its duty as well as its privilege to do all in its power to acquaint the doctors of the world with matters of interest and importance to them and to be the medium through which doctors may assist all mankind to attain the highest possible level of health.

Very shortly after the September conference in London, the American Medical Association indicated its willingness to join the World Medical Association and give support to its aims and objects. I am sure my colleagues of the organizing committee, and the medical associations scattered throughout the world, would wish me to say that the World Medical Association was heartened indeed by this action on your part. This great Association with more than 130,000 members, committed to the lofty purpose of saving human lives, can be a tower of strength to the rest of the world in promoting those ideals and objectives which are so essential to human health and happiness.

One does not need to be a seer or a prophet to recognize the chaotic state in which the world now finds itself, and the danger signals which rear their heads as a threat to future world peace. Surely, we of the healing arts, whose lives are dedicated to the saving of human lives rather than to their destruction, have a tremendous part to play in promoting international good will and understanding. We are not concerned with political squabbles, territorial aggrandizement or economic bargaining. We have nothing to sell to one another but we have much to give to each other. We go into one another's countries, not looking for profit but bearing gifts. Surely our slogan, whether we be black men, white men or yellow men, is "What Can We Do to Help You?"

As the *British Medical Journal* so well says in its issue of May 3, "It is clear that world medicine, having no ax to grind, and being above politics and ideology, can exert a salutary influence in world affairs. Closer contact of the members of the profession throughout the world must surely advance international friendship and good will." If I might be so bold as to suggest an additional objective to this influential Association for its second hundred year period, it would be that you support enthusiastically the world movement in medicine with the same courage and devotion, strength and vision as you have done during the past hundred years in establishing in this great country the high place which you now enjoy and so rightly deserve.

Humanity faces a grave decision. We must either go forward as one world or run the risk of going into utter darkness blacker than the dark ages ever saw. We in medicine—worldwide medicine—have a vitally important part to play in promoting world health and world peace. In the immortal words of Dr. John McCrae, who said "To you from failing hands we throw the torch; be yours to hold it high"—may I say that we of the healing arts must hold that torch high—so high that it will be a light to the footsteps of mankind everywhere; and, once having seen the light and measured its beauty and appreciated its guidance, mankind will refuse to see that light go out. Surely, mankind will choose to live in peace rather than to die in war.

Dr. George F. Lull, Secretary, stated that the Association had received many telegrams and resolutions, which he did not read, among them being a very beautiful printed resolution from the Swiss Academy of Medical Sciences, signed by the President and the Secretary-General; a telegram from the Guild of Prescription Opticians of America, congratulating the Association on its hundredth anniversary; congratulations and best wishes from the Louisiana State Nurses Association; congratulations and best wishes from the Korean Medical Association, National Department of Public Health and Welfare; best wishes from Dr. Hector Valle Pineda, president of the Havana Medical Association, and from the Pan American Medical Association; congratulations and extending his appreciation from Professor Arthur Stoll, Basel, Switzerland; greetings and congratulations from the *Medical Journal of Australia;* congratulations from the American Surgical Trade Association, an organization whose membership is dedicated to service the medical profession, and from Dr. Robert P. Fischelis, secretary of the American Pharmaceutical Association; a letter from the representative of the National Health Administration of China, who will appear before the House at a later date, as he has a presentation to make at that time; a set of resolutions from the Philippine Medical Association, which Dr. Fishbein has already published in THE JOURNAL; this beautiful set of resolutions, which were to have been presented in person by Father Schwitalla, the very good friend of many of us, for the Catholic Hospital Association (As you know, Father Schwitalla was taken ill and could not come to the meeting but he sent a representative, and these resolutions were presented), and a very interesting resolution from the home office, from the Chapel of the Typographical Union, which says, in part, "This Chapel in regular meeting assembled on the 28th day of May goes on record as extending to the American Medical Association our heartiest felicitations on its One Hundredth Anniversary."

The Speaker requested the Secretary to make appropriate acknowledgments of all of these resolutions.

Supplementary Report of Judicial Council

Dr. Louis A. Buie, member of the Judicial Council, reported as follows: I am speaking on behalf of the Judicial Council. Having observed the difficulties that have arisen this morning, which arose in December, in an attempt on the part of the House of Delegates to do what every one considers to be proper in the adoption of the Constitution and By-Laws in revised form, and realizing that it is possible that some of these difficulties might have been obviated by a response to the request of the chairman of the committee which was appointed to revise the Constitution and By-Laws, of which I am also a member, that request being that the revised copy of the Constitution and By-Laws which was sent to each member of the House of Delegates a month ago be studied carefully and that suggestions be sent to the committee in order that these adjustments might be made prior to this meeting, further, that any of those who wished to discuss any vital points, such as a conflict between the By-Laws and the Constitution, as was brought out by Dr. Bunce, should come before this committee at its meeting last Saturday morning at 10 o'clock, when all of us were present and when only one individual came to present any problem, that being Dr. Henderson of the Board of Trustees—realizing all of those facts and because of the fact that the Judicial Council has in prospect and is now working on the problem of a revision of the Principles of Medical Ethics, or a rearrangement if you wish, I don't know that you can change principles any more than you can change the Ten Commandments, but with changing times and conditions we realize that certain readjustments can be made.

I make these few remarks, Mr. Speaker, because I wish to try to avoid a similar circumstance when we come to the time of presenting to this body our suggestions and your suggestions concerning an alteration in the Principles of Medical Ethics which have guarded this Association for one hundred years.

I should like to call your attention to the fact that when this responsibility was laid on the Judicial Council at the meeting of the American Medical Association in San Francisco last July, the Chairman of the Council arose and requested that suggestions be sent to this Council concerning these revisions. As the Chairman of the Council read in his supplementary report yesterday (it might have been overlooked; consequently I repeat it now), only three letters have been received during the period of a year which has elapsed. So, if there are any suggestions which you have concerning this important revision of the Principles of Medical Ethics, we will certainly be very grateful to you if you will send them in to us, the members of the Judicial Council who are charged with the responsibility of making a revision which must be approached cautiously and must be done in order that it may have lasting value.

On behalf of the Committee to Study a Revision of Constitution and By-Laws, I should like to say that we are perfectly willing to continue our efforts in regard to carrying forward this task of the revision as you would like to have it.

Report of the Reference Committee on Amendments to the Constitution and By-Laws

Dr. Britton E. Pickett Sr., Chairman, presented the following report:

1. Because of the desirability of conferring Honorary Fellowship on certain distinguished foreign guests, your committee recommends that chapter XII, section 7, of the present By-Laws of the American Medical Association be amended to read as follows: "Physicians of foreign countries who have risen to prominence in the profession of medicine and who are in attendance at the session may be elected to Honorary Fellowship by the House of Delegates on the nomination of the Council on Scientific Assembly. The several sections may make recommendations to the Council on Scientific Assembly regarding individuals for such nomination."

2. Your committee has considered the supplementary report of the Judicial Council pertaining to the revision of the Principles of Medical Ethics and approves the report in its entirety.

Respectfully submitted,

Britton E. Pickett Sr, Chairman.
L. G. Christian.
Allen H Bunce.
Homer Lee Pearson Jr.
Alfred S. Giordano.

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Thomas S. Cullen, Maryland, and carried that the first section of the report of the reference committee be adopted.

Dr. Bedell then moved that chapter XII, section 7, of the By-Laws be amended to conform with the report of the reference committee. The motion was seconded by Dr. James C. Sargent, Wisconsin, and carried, and the Speaker declared the By-Laws so amended.

The second section of the report of the reference committee, approving the supplementary report of the Judicial Council dealing with revision of the Principles of Medical Ethics, was adopted on motion of Dr. Pickett, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried after discussion.

On motion of Dr. Pickett, seconded by Dr. Thomas S. Cullen, Maryland, and carried, the report of the reference committee was adopted as a whole.

NEW BUSINESS

Resolutions on Sections Celebrating Their Centennials

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolutions, which were referred to the Reference Committee on Sections and Section Work:

Whereas, Centennial celebrations are excellent for our spirits and morale, and aid in stimulating further accomplishments in this country of ours; and

Whereas, The medical profession has every reason to be proud of and to publicize our scientific progress, and

Whereas, The sections of the American Medical Association have been established at varying times with reports and records of the contributions of specialists and general practitioners, be it

Resolved, That the sections of the American Medical Association likewise observe the centennials and anniversaries of their establishment with appropriate ceremonies, noting the records of achievements in the particular specialty, to center attention on scientific progress as a part of the history of the American Medical Association; and be it further

Resolved, That funds be appropriated as may be necessary

Resolutions on Hospital Relationships—Specialty Board Relationships

Dr. John J. Masterson, New York, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

Whereas, The house of delegates of the Medical Society of the State of New York on May 7, 1947 adopted the following resolutions: and

"Whereas, It is the policy and aim of the American Medical Association to foster affiliation of all physicians with a hospital in order that they may continue their education and increase their efficiency; and

"Whereas, Interference in doctor hospital relationship is influenced by the indirect action of the various specialty boards; and

"Whereas, On account of the numerous complaints from returning veterans being unable to qualify for a board on account of a lack of available acceptable residencies; and

"Whereas, This condition is prevalent throughout the country; therefore be it

"*Resolved*, That delegates of the Medical Society of the State of New York be directed to memorialize the House of Delegates of the American Medical Association at its forthcoming June meeting in Atlantic City that the Board of Trustees be requested to appoint a committee for the purpose of investigating the hospital specialty board relationships and to take whatever means necessary to correct the situation," therefore be it

Resolved, That the House of Delegates of the American Medical Association approves the foregoing and requests the Board of Trustees to be guided accordingly.

Resolutions on Safety in Flying

Dr. Floyd S. Winslow, New York, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

Whereas, It has been brought to the attention of the American Medical Association that a condition detrimental to the public interest has developed with reference to safety in flying, as evidenced by the adoption of the following resolution by the Aero Medical Association on June 6, 1947:

> Whereas, The Civil Aeronautics Administration during the past three years has lowered the physical standards for private and student pilots, and
>
> Whereas, The Civil Aeronautics Administration has permitted physical examinations of private and student pilots to be made by physicians without training in aviation medicine, and
>
> Whereas, The Civil Aeronautics Administration has still further lowered the safeguards of physical qualifications by permitting the examinations of these two grades of pilots to be made by persons whose education and training do not qualify them as doctors of medicine and in some instances by persons who are untrained even in the basic medical sciences; and
>
> Whereas, These actions of the Civil Aeronautics Administration have been taken contrary to authoritative medical advice and are, in the opinion of the Aero Medical Association, fraught with danger to the public and to aeronautics and have resulted in deluding the public with a false sense of security, therefore be it
>
> *Resolved*, By the Aero Medical Association of the United States, at its 18th annual meeting in Atlantic City, N J, June 3 to 6, 1947, that it condemns these dangerous policies of the Civil Aeronautics Administration, and be it further
>
> *Resolved*, That in the opinion of the association, physical examinations of all grades of pilots should be conducted only by those who are doctors of medicine and who have some training in aviation medicine, and be it further
>
> *Resolved*, That these resolutions be published and copies transmitted to the Secretary of Commerce and to the appropriate Committees of Congress,

Whereas, The American Medical Association is in accord with the opinion and action of the Aero Medical Association, therefore be it

Resolved, By the House of Delegates of the American Medical Association at its annual session in Atlantic City, N J, that it endorses these resolutions adopted by the Aero Medical Association on June 6, 1947, and be it further

Resolved, That the Board of Trustees be authorized to take such action as deemed advisable by the Board to further maximum safety in flying

Resolution on Increasing Pay of Medical Officers in the Several Services

Dr. James C. Sargent, Wisconsin, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The procurement of an adequate number of qualified medical officers for the armed forces has come to be a most critical problem, and

Whereas, It is the expressed belief of those in authority that this situation is due largely to the present discrepancy between military and civilian medical practice in the matters of income and opportunities for professional advancement; therefore be it

Resolved, That the House of Delegates go on record commending and encouraging the present efforts of the War and Navy departments and the Public Health Service in securing legislation raising the professional standards and increasing the pay of the medical officers within the several services

It is not the purpose or intention of the World Medical Association to intrude into those affairs which constitutionally belong to individual associations and countries The World Medical Association is not a super body, desiring to dictate to any one. On the contrary, the World Medical Association conceives it to be its duty as well as its privilege to do all in its power to acquaint the doctors of the world with matters of interest and importance to them and to be the medium throug' which doctors may assist all mankind to attain the highest p sible level of health.

Resolutions on Inclusion of General Practitioners on Staffs of Hospitals

Dr Thomas A. McGoldrick, New York, presented the following resolutions, which were referred to the Reference Committee on General Medical Practice:

These resolutions are presented at the direction of the Medical Society of the County of Kings located in Brooklyn, which is composed of 3,400 members of the American Medical Association

The delegates of Kings County are directed to introduce these resolutions

Resolved, That the American Medical Association urge the inclusion of general practitioners on the staff of approved hospitals, and

Resolved, That recognition of hospitals shall not be jeopardized by the American medical colleges or colleges of special branches of medicine because of the fact that they include general practitioners on their staff; and

Resolved, That all physicians, before being rated as specialists, should spend an adequate number of years in general practice, and

Resolved, That training in hospital wards and dispensaries be accepted as a qualification for a specialist in lieu of a full time residency

Resolution on Care of Veterans

Dr. Herbert H. Bauckus, New York, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business

Whereas, The veterans suffering from injury or disease incurred during service in the armed forces deserve not only great sympathy from the community but medical care second to none; and

Whereas, In several states, through the operation of workmen's compensation laws, the highest type of medical and surgical care is provided for injured workers, and

Whereas, The majority of patients in veterans' hospitals are those with non service connected disabilities, and the Veterans Administration contemplates the erection of enormously increased facilities, primarily to take care of veterans' non service connected disabilities; and

Whereas, It would be false economy to deprive the veterans with service connected disabilities of the finest medical care; therefore, be it

Resolved, That the House of Delegates of the American Medical Association urge the President of the United States and the administrator of veterans' affairs to continue and augment the existing "home town" medical care program

Q Graves, Louisiana, presented the following
ich was referred to the Reference Committee on
d Public Relations:

is commonly known that application papers under the
rcotic Act must be notarized when a physician first
cial tax stamps; and

ler this same act notarization is not required for

required that the declaration of narcotics on hand
accompany the application for renewal of stamps and
e notarized; and

second notarization appears useless and unnecessary,

the House of Delegates of the American Medical
h the proper channels appeal to the Collector of
in Washington for the discontinuance of this require
notarization

Placing Statue of Dr. William Crawford . New York University Hall of Fame for Great Americans

Dr. Lloyd Noland, Alabama, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

Whereas, Dr. *William Crawford Gorgas,* native son of Alabama, Surgeon General of the United States Army, 1914-1918, passed away July 4, 1920, having served his country in war and in peace with rare skill and ability, thereby reflecting fame and distinction on the medical profession of his native state of Alabama and on that of the nation; and

Whereas, In May 1937 a bust of Dr Gorgas was placed on the capitol grounds at Montgomery with the authority and approval of this association, on which was a tablet describing Dr. Gorgas as "A Servant of Mankind and A Benefactor to Humanity" and further expressing the sentiment of this association in respect to his work, that "his vision and his initiative translated the known scientific facts concerning yellow fever into practical accomplishment, thereby making possible the control of this scourge of the tropics and the building of the Panama Canal"; and

Whereas, The *judgment of the medical profession of America* was suitably expressed by that eminent member of the profession, Dr William H Welch, while President of the American Medical *Association in 1912, when presenting Dr Gorgas at Johns Hopkins for* an honorary degree as follows

"In behalf of the Academic Council, I have the honor to present for the *honorary degree of Doctor of Laws Dr William Crawford* Gorgas, Colonel in the Medical Corps of the United States Army, member of the Isthmian Canal Commission, and Chief Sanitary Officer *of the Isthmian Canal Zone, formerly President of the American* Medical Association, physician and sanitarian of the highest eminence, who, by his conquest over pestilential diseases, has rendered signal *service to his profession, to his country, and to the world*

"With high administrative capacity and with full command of the resources of sanitary science, Colonel Gorgas has given to the world the *most complete and impressive demonstration in medical history* of the accuracy and the life saving power of our new knowledge concerning the causation and mode of spread of certain dreaded epidemic and endemic diseases

"He it was who, by application of the discoveries of Major Reed and his colleagues of the Army Yellow Fever Commission, was mainly *instrumental in freeing Cuba of yellow fever and he it is who,* in spite of obstacles and embarrassments, has made the construction of the Isthmian Canal possible without serious loss of life or incapacity *from disease—a triumph of preventive medicine not surpassed* in importance and significance by the achievements of the engineer.

"In the conquest of science over disease, in the saving of untold *thousands of human lives and of human treasure, in the protection* of our shores from a formerly ever threatening scourge, in the reclamation to civilization of tropical lands, in results such as these are to be *found the monuments of our laureate,* his victories of peace, to which this university would now bear testimony by such honor as it can bestow", now therefore be it

Resolved, By the Medical Association of the State of Alabama in annual convention assembled at Birmingham on April 14-16, 1947 that it is the judgment of this association that William Crawford Gorgas is *worthy of election to the New York University* Hall of Fame for Great Americans, and that steps should be taken to that end, and be it further

Resolved, That this resolution be presented by the delegates from this association to the House of Delegates of the American Medical Association at its next annual meeting, with the view that a suitable resolution may be adopted by that Association, endorsing and concurring in the action of this association, and be it further

Resolved, That a committee be appointed by the President of this Association, to take such other steps as may seem expedient to carry out the purpose of this resolution.

Resolution on Hospital Standardization

Dr. Edward H. McLean, Oregon, presented the following resolution, which was referred to the Reference Committee on Medical Education:

Whereas, The Council on Medical Education and Hospitals, through the establishment of standards for hospitals and their periodic inspection, has contributed materially to the development of high type hospital service and to proficient professional care in hospitals; and

Whereas, The American College of Surgeons has also established hospital standards and carries on periodic inspection; and

Whereas, The American College of Surgeons, representing as it does the surgical specialties, has placed primary emphasis on this phase of medical service in hospitals; and

Whereas, The interests of the public and the medical profession as a whole are best served by the establishment and enforcement of standards which give due weight to all the various phases of medical practice; therefore be it

Resolved, That the Council on Medical Education and Hospitals be authorized and directed to review the various existing forms of hospital standardization and in cooperation with the constituent state medical associations promulgate and enforce new and up to date standards that reflect the needs of all phases of medical service and professional care in hospitals.

Resolutions on Training of Medical Students to Administer Programs of Health and Medical Services in Schools and in Industry

Dr. Clifford C. Sherburne, Ohio, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

Whereas, The establishment of a central, coordinating unit to administer programs of health and medical services and health educational activities in universities, colleges, secondary school systems and industry is being attempted in many communities in an effort to bring about efficient and economical operation of such programs; therefore be it

Resolved, That so far as practical, the administration of such programs should be under the leadership and control of a doctor of medicine, possessing administrative ability and with experience and training in the technics of preventive medicine and health education; and be it further

Resolved, That all schools of medicine be urged to provide training which will equip graduates for administrative work of this character in order that leadership and coordination may be furnished by medically trained administrators.

Resolutions on Hospital Competition with Private Practice

Dr. B. R. Kirklin, Section on Radiology, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, Incorporated voluntary hospitals in several communities have urged physicians, either by letter or word of mouth, to refer ambulatory patients to the hospital for diagnostic and therapeutic medical services to be rendered by specialists in the hospital; and

Whereas, For the purpose of increasing their profits from these medical procedures some hospital administrators have even stated that they would withdraw staff privileges from physicians and surgeons who refused to refer their patients to the hospital for these outpatient medical services; and

Whereas, Such competition of hospital corporations with private practicing physicians who maintain private offices and the use of such tactics to obtain outpatients for the hospital to its own profit is in violation of the Principles of Medical Ethics and the policies of organized medicine and contrary to the best interests of the patients involved; therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby expresses its emphatic disapproval of such practices which place hospital corporations in the practice of medicine in direct competition with private practicing physicians; and be it further

Resolved, That the Council on Medical Education and Hospitals of the American Medical Association be instructed to convey the sense of these resolutions to all hospitals registered by said Council; and be it further

Resolved, That a copy of these resolutions be transmitted to the American College of Surgeons with the request that its Committee on Hospital Standardization bring said resolutions to the attention of the administrators of hospitals which they inspect.

Resolution on Dissemination of Information Pertaining to Matters of Public Health

Dr. Arthur J. Bedell, Section on Ophthalmology, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business, with the suggestion that that committee call on the Judicial Council if it sees fit:

Whereas, It is not contrary to the Principles of Medical Ethics as determined by the American Medical Association for members of the Association to disseminate information pertaining to matters of public health, such as cancer, diabetes, venereal disease and other conditions, by lectures, demonstrations, radio talks, pamphlets, conferences or other means to nonmedical groups; and

Whereas, Ophthalmic subjects such as vascular disease, glaucoma, retinal disorders, optic nerve disease and so on, considered as potential causes of blindness, are matters of grave importance to the public; and

Whereas, The prevention of blindness is one of the chief obligations of ophthalmologists; therefore be it

Resolved, That the Section on Ophthalmology of the American Medical Association declares that it is entirely within the definition of medical ethics for its members to engage in lectures, demonstrations, the preparation of pamphlets and other measures suitable for the dissemination of information designed to prevent blindness, and directed to any nonmedical group.

Resolution on Clarification of Rules Relating to Medical Service Fees Received from the Federal Government

Dr. Thomas D. Cunningham, Colorado, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, Many members of the American Medical Association are now being remunerated financially by various branches of the federal government as the result of pension rights or retirement pay from the Army or Navy and for services rendered as Veterans Administration consultants, teachers in Veterans Administration institutions, experts in federal compensation cases or as participants in "Hometown Care Plans"; and

Whereas, Much confusion now prevails regarding the numerous rules, regulations and directives of the various branches, bureaus, agencies and commissions of the federal government; and

Whereas, The receipt of income from one branch of the federal government would seem in certain instances to preclude the acceptance of fees from other branches of government; now therfore be it

Resolved, That the House of Delegates of the American Medical Association instruct the Editor of The Journal of the American Medical Association and the Bureau of Legal Medicine and Legislation to collect, annotate, analyze, interpret and publish a digest of all the rules and regulations of the federal government pertaining to medical practice and medical service fees.

Resolution on Change of Policy of American Specialty Boards

Dr. Thomas D. Cunningham, Colorado, presented by title a Resolution on Change of Policy of American Specialty Boards, which was referred to the Reference Committee on General Medical Practice. The resolution reads:

Whereas, Certain of the American specialty boards not only refuse to grant credit for experience and training acquired in the field of general practice but have also recently announced discontinuance of their former practice of according credit for preceptorships with a certified diplomate and have ruled instead that every applicant for certification must serve a lengthy residency following his internship; and

Whereas, This recent change in policy constitutes an unfair imposition on many returned medical veterans and other young physicians who find it impossible to obtain such residencies; and

Whereas, Doctors entering the various specialties without any experience or training in the field of general practice find it difficult, if not impossible, to develop a broad overall understanding of the field of medicine as a whole, and

Whereas, General practice offers unique opportunities for the development of individual initiative, self reliance, personality development and professional growth; and

Whereas, It is the opinion of the American Medical Association that general practice and preceptorships are two of the best methods of teaching the art of medicine; and

Whereas, Qualified and experienced preceptors already certified by these boards are available in all parts of the United States; and

Whereas, The art of medicine is frequently neglected in hospital residencies owing to overemphasis on the science of medicine; now therefore be it

Resolved, That the House of Delegates of the American Medical Association requests the Advisory Board for Medical Specialties and the several American specialty boards to review and reconsider their policies in relation to general practice, residencies and preceptorships in accordance with the foregoing statements.

Resolutions on Effective Program of Public Relations

Dr. Robertson Ward, California, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, The House of Delegates has authorized and endorsed an effective program of public relations for the American medical profession; and

Whereas, The American Medical Association is the only organization which is qualified to speak with authority for American medicine; now therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby requests and urges the Board of Trustees of the Association to provide sufficient funds in each annual budget of the Association for the conduct of the Association's public relations program; and be it further

Resolution on Group Practice

Dr. J. Stanley Kenney, New York, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, Group practice is of increasing interest in the profession because of various prepayment plans which seek to encourage the practice of medicine in groups; and

Whereas, There are no largely accepted principles or rules governing the practice of medicine in groups; and

Whereas, It is desirable that the American Medical Association supervise this development rather than forfeit it to organizations not affiliated with organized medicine; therefore be it

Resolved, That the delegates to the Medical Society of the State of New York instruct its delegates to the American Medical Association to propose a resolution to that body that will bring about provision by the American Medical Association for the establishment of a bureau or council on group practice. The functions of such bureau will be: (*a*) to serve as a clearing house of information on group practice throughout the United States; (*b*) to formulate professional, ethical and other principles governing the development of such group practice, and (*c*) ultimately, at its discretion, to provide for qualifications and recognition of groups engaged in group practice in the various parts of this country.

Resolutions on S. 140

Dr. Thomas K. Lewis, New Jersey, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, Senate bill 140, sponsored by Senators Fulbright and Taft, which would create a Department of Health, Education and Welfare, has been favorably reported by the Senate Committee on Expenditures in the Executive Departments, and

Whereas, The American Medical Association has consistently advocated placing all health activities of the federal government, except those of the Army, Navy and Veterans Administration, in a single agency or department concerned solely with health; and

Whereas, S. 140 does not conform to this objective; therefore be it

Resolved, That the House of Delegates of the American Medical Association expresses its unalterable disapproval of S. 140; and be it further

Resolved, That the sponsors of this measure and all other members of the Senate and of the House of Representatives be appraised of this action; and be it further

Resolved, That the constituent state associations be urged to take similar action.

Resolutions on Inclusion of General Practitioners on Staffs of Hospitals

Dr. Thomas A. McGoldrick, New York, presented the following resolutions, which were referred to the Reference Committee on General Medical Practice:

These resolutions are presented at the direction of the Medical Society of the County of Kings located in Brooklyn, which is composed of 3,400 members of the American Medical Association.

The delegates of Kings County are directed to introduce these resolutions:

Resolved, That the American Medical Association urge the inclusion of general practitioners on the staff of approved hospitals; and

Resolved, That recognition of hospitals shall not be jeopardized by the American medical colleges or colleges of special branches of medicine because of the fact that they include general practitioners on their staff; and

Resolved, That all physicians, before being rated as specialists, should spend an adequate number of years in general practice; and

Resolved, That training in hospital wards and dispensaries be accepted as a qualification for a specialist in lieu of a full time residency.

Resolution on Care of Veterans

Dr. Herbert H. Bauckus, New York, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The veterans suffering from injury or disease incurred during service in the armed forces deserve not only great sympathy from the community but medical care second to none; and

Whereas, In several states, through the operation of workmen's compensation laws, the highest type of medical and surgical care is provided for injured workers; and

Whereas, The majority of patients in veterans' hospitals are those with non-service connected disabilities, and the Veterans Administration contemplates the erection of enormously increased facilities, primarily to take care of veterans' non-service connected disabilities; and

Whereas, It would be false economy to deprive the veterans with service connected disabilities of the finest medical care; therefore, be it

Resolved, That the House of Delegates of the American Medical Association urge the President of the United States and the administrator of veterans' affairs to continue and augment the existing "home town" medical care program.

Resolution Requesting Discontinuance of Notarization of Declaration of Narcotics on Hand to Accompany Renewal of Stamps

Dr. James Q. Graves, Louisiana, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Whereas, It is commonly known that application papers under the Harrison Antinarcotic Act must be notarized when a physician first registers for special tax stamps; and

Whereas, Under this same act notarization is not required for renewal; and

Whereas, It is required that the declaration of narcotics on hand (inventory) must accompany the application for renewal of stamps and such form must be notarized; and

Whereas, This second notarization appears useless and unnecessary; be it

Resolved, That the House of Delegates of the American Medical Association through the proper channels appeal to the Collector of Internal Revenue in Washington for the discontinuance of this requirement in regard to notarization.

Resolutions on Placing Statue of Dr. William Crawford Gorgas in New York University Hall of Fame for Great Americans

Dr. Lloyd Noland, Alabama, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

Whereas, Dr. William Crawford Gorgas, native son of Alabama, Surgeon General of the United States Army, 1914-1918, passed away July 4, 1920, having served his country in war and in peace with rare skill and ability, thereby reflecting fame and distinction on the medical profession of his native state of Alabama and on that of the nation; and

Whereas, In May 1937 a bust of Dr. Gorgas was placed on the capitol grounds at Montgomery with the authority and approval of this association, on which was a tablet describing Dr. Gorgas as "A Servant of Mankind and A Benefactor to Humanity" and further expressing the sentiment of this association in respect to his work, that "his vision and his initiative translated the known scientific facts concerning yellow fever into practical accomplishment, thereby making possible the control of this scourge of the tropics and the building of the Panama Canal"; and

Whereas, The judgment of the medical profession of America was suitably expressed by that eminent member of the profession, Dr. William H. Welch, while President of the American Medical Associaton in 1912, when presenting Dr. Gorgas at Johns Hopkins for an honorary degree as follows:

"In behalf of the Academic Council, I have the honor to present for the honorary degree of Doctor of Laws Dr. William Crawford Gorgas, Colonel in the Medical Corps of the United States Army, member of the Isthmian Canal Commission, and Chief Sanitary Officer of the Isthmian Canal Zone, formerly President of the American Medical Association, physician and sanitarian of the highest eminence, who, by his conquest over pestilential diseases, has rendered signal service to his profession, to his country, and to the world.

"With high administrative capacity and with full command of the resources of sanitary science, Colonel Gorgas has given to the world the most complete and impressive demonstration in medical history of the accuracy and the life-saving power of our new knowledge concerning the causation and mode of spread of certain dreaded epidemic and endemic diseases.

"He it was who, by application of the discoveries of Major Reed and his colleagues of the Army Yellow Fever Commission, was mainly instrumental in freeing Cuba of yellow fever and he it is who, in spite of obstacles and embarrassments, has made the construction of the Isthmian Canal possible without serious loss of life or incapacity from disease—a triumph of. preventive medicine not surpassed in importance and significance by the achievements of the engineer.

"In the conquest of science over disease, in the saving of untold thousands of human lives and of human treasure, in the protection of our shores from a formerly ever threatening scourge, in the reclamation to civilization of tropical lands, in results such as these are to be found the monuments of our laureate, his victories of peace, to which this university would now bear testimony by such honor as it can bestow"; now therefore be it

Resolved, By the Medical Association of the State of Alabama in annual convention assembled at Birmingham on April 14-16, 1947 that it is the judgment of this association that William Crawford Gorgas is worthy of election to the New York University Hall of Fame for Great Americans, and that steps should be taken to that end; and be it further

Resolved, That this resolution be presented by the delegates from this association to the House of Delegates of the American Medical Association at its next annual meeting, with the view that a suitable resolution may be adopted by that Association, endorsing and concurring in the action of this association; and be it further

Resolved, That a committee be appointed by the President of this Association, to take such other steps as may seem expedient to carry out the purpose of this resolution.

Resolution on Hospital Standardization

Dr. Edward H. McLean, Oregon, presented the following resolution, which was referred to the Reference Committee on Medical Education:

Whereas, The Council on Medical Education and Hospitals, through the establishment of standards for hospitals and their periodic inspection, has contributed materially to the development of high type hospital service and to proficient professional care in hospitals, and

Whereas, The American College of Surgeons has also established hospital standards and carries on periodic inspection; and

Whereas, The American College of Surgeons, representing as it does the surgical specialties, has placed primary emphasis on this phase of medical service in hospitals; and

Whereas, The interests of the public and the medical profession as a whole are best served by the establishment and enforcement of standards which give due weight to all the various phases of medical practice; therefore be it

Resolved, That the Council on Medical Education and Hospitals be authorized and directed to review the various existing forms of hospital standardization and in cooperation with the constituent state medical associations promulgate and enforce new and up to date standards that reflect the needs of all phases of medical service and professional care in hospitals

Resolutions on Training of Medical Students to Administer Programs of Health and Medical Services in Schools and in Industry

Dr. Clifford C. Sherburne, Ohio, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

Whereas, The establishment of a central, coordinating unit to administer programs of health and medical services and health educational activities in universities, colleges, secondary school systems and industry is being attempted in many communities in an effort to bring about efficient and economical operation of such programs; therefore be it

Resolved, That so far as practical, the administration of such programs should be under the leadership and control of a doctor of medicine, possessing administrative ability and with experience and training in the technics of preventive medicine and health education; and be it further

Resolved, That all schools of medicine be urged to provide training which will equip graduates for administrative work of this character in order that leadership and coordination may be furnished by medically trained administrators

Resolutions on Hospital Competition with Private Practice

Dr. B R. Kirklin, Section on Radiology, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, Incorporated voluntary hospitals in several communities have urged physicians, either by letter or word of mouth, to refer ambulatory patients to the hospital for diagnostic and therapeutic medical services to be rendered by specialists in the hospital, and

Whereas, For the purpose of increasing their profits from these medical procedures some hospital administrators have even stated that they would withdraw staff privileges from physicians and surgeons who refused to refer their patients to the hospital for these outpatient medical services; and

Whereas, Such competition of hospital corporations with private practicing physicians who maintain private offices and the use of such tactics to obtain outpatients for the hospital to its own profit is in violation of the Principles of Medical Ethics and the policies of organized medicine and contrary to the best interests of the patients involved, therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby expresses its emphatic disapproval of such practices which place hospital corporations in the practice of medicine in direct competition with private practicing physicians, and be it further

Resolved, That the Council on Medical Education and Hospitals of the American Medical Association be instructed to convey the sense of these resolutions to all hospitals registered by said Council, and be it further

Resolved, That a copy of these resolutions be transmitted to the American College of Surgeons with the request that its Committee on Hospital Standardization bring said resolutions to the attention of the administrators of hospitals which they inspect

Resolution on Dissemination of Information Pertaining to Matters of Public Health

Dr. Arthur J. Bedell, Section on Ophthalmology, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business, with the suggestion that that committee call on the Judicial Council if it sees fit:

Whereas, It is not contrary to the Principles of Medical Ethics as determined by the American Medical Association for members of the Association to disseminate information pertaining to matters of public health, such as cancer, diabetes, venereal disease and other conditions, by lectures, demonstrations, radio talks, pamphlets, conferences or other means to nonmedical groups; and

Whereas, Ophthalmic subjects such as vascular disease, glaucoma, retinal disorders, optic nerve disease and so on, considered as potential causes of blindness, are matters of grave importance to the public; and

Whereas, The prevention of blindness is one of the chief obligations of ophthalmologists, therefore be it

Resolved, That the Section on Ophthalmology of the American Medical Association declares that it is entirely within the definition of medical ethics for its members to engage in lectures, demonstrations, the preparation of pamphlets and other measures suitable for the dissemination of information designed to prevent blindness, and directed to any nonmedical group

Resolution on Clarification of Rules Relating to Medical Service Fees Received from the Federal Government

Dr. Thomas D Cunningham, Colorado, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, Many members of the American Medical Association are now being remunerated financially by various branches of the federal government as the result of pension rights or retirement pay from the Army or Navy and for services rendered as Veterans Administration consultants, teachers in Veterans Administration institutions, experts in federal compensation cases or as participants in "Hometown Care Plans"; and

Whereas, Much confusion now prevails regarding the numerous rules, regulations and directives of the various branches, bureaus, agencies and commissions of the federal government, and

Whereas, The receipt of income from one branch of the federal government would seem in certain instances to preclude the acceptance of fees from other branches of government, now therfore be it

Resolved, That the House of Delegates of the American Medical Association instruct the Editor of The Journal of the American Medical Association and the Bureau of Legal Medicine and Legislation to collect, annotate, analyze, interpret and publish a digest of all the rules and regulations of the federal government pertaining to medical practice and medical service fees

Resolution on Change of Policy of American Specialty Boards

Dr. Thomas D. Cunningham, Colorado, presented by title a Resolution on Change of Policy of American Specialty Boards, which was referred to the Reference Committee on General Medical Practice. The resolution reads:

Whereas, Certain of the American specialty boards not only refuse to grant credit for experience and training acquired in the field of general practice but have also recently announced discontinuance of their former practice of according credit for preceptorships with a certified diplomate and have ruled instead that every applicant for certification must serve a lengthy residency following his internship, and

Whereas, This recent change in policy constitutes an unfair imposition on many returned medical veterans and other young physicians who find it impossible to obtain such residencies, and

Whereas, Doctors entering the various specialties without any experience or training in the field of general practice find it difficult, if not impossible, to develop a broad overall understanding of the field of medicine as a whole, and

Whereas, General practice offers unique opportunities for the development of individual initiative, self reliance, personality development and professional growth, and

Whereas, It is the opinion of the American Medical Association that general practice and preceptorships are two of the best methods of teaching the art of medicine, and

Whereas, Qualified and experienced preceptors already certified by these boards are available in all parts of the United States, and

Whereas, The art of medicine is frequently neglected in hospital residencies owing to overemphasis on the science of medicine, now therefore be it

Resolved, That the House of Delegates of the American Medical Association requests the Advisory Board for Medical Specialties and the several American specialty boards to review and reconsider their policies in relation to general practice, residencies and preceptorships in accordance with the foregoing statements

Resolutions on Effective Program of Public Relations

Dr. Robertson Ward, California, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, The House of Delegates has authorized and endorsed an effective program of public relations for the American medical profession, and

Whereas, The American Medical Association is the only organization which is qualified to speak with authority for American medicine, now therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby requests and urges the Board of Trustees of the Association to provide sufficient funds in each annual budget of the Association for the conduct of the Association's public relations program, and be it further

Resolved, That if the Board of Trustees is convinced that the Association cannot afford to carry out a public relations program as heretofore approved by the House of Delegates, membership dues payable by each member of the Association be established as soon as possible, such dues to be not more than $10 per annum

Resolution on News Releases of American Medical Association

Dr. Harry Aranow, New York, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The American Medical Association issues a news release each Friday on the content of articles appearing in the forthcoming Journal of the American Medical Association, and

Whereas, These releases reach the public through the newspapers before the physicians have received the copies of their Journal containing the complete article; and

Whereas, Patients partially informed through these releases frequently ask their physicians about such items, and

Whereas, These questions have been a source of embarrassment to the medical profession and have tended to affect adversely the confidence placed by the patient in the doctor's knowledge of current scientific advances, therefore be it

Resolved, That such advance press items either be discontinued altogether or be released after actual receipt by the medical profession of The Journal of the American Medical Association

Resolution on Deductible Items for Federal Income Tax Purposes

Dr. L G Christian, Michigan, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The expenses of attending conventions, including medical conventions, are now deductible in federal income tax compilations, and

Whereas, The expenses of attending medical postgraduate meetings and conferences are not allowed as deductible items for federal income tax purposes, therefore be it

Resolved, That the House of Delegates of the American Medical Association request the Board of Trustees to contact the proper governmental agencies to put this into effect

Resolution on Nursing Shortage

Dr. Walter W. Mott, New York, presented the following resolution, which was referred to the Reference Committee on Medical Education.

Whereas, There is a nationwide nurse scarcity of alarming proportions, with recently compiled statistics indicating a national shortage of 40,000 nurses, 16 per cent of the hospitals in the United States with closed beds, and 33,000 beds in our hospitals unavailable because of this nurse shortage, and

Whereas, In the month of April 1947 in New York State, hospitals reported 1,831 closed beds and waiting lists of 8,463 patients, primarily because of nurse shortage, and

Whereas, The national enrolment of 31,000 students in approved schools of nursing in 1946 was some 13,000 fewer than the schools sought, and approximately 40 per cent fewer than the 1945 enrolment, and

Whereas, This trend and the actual shortage are of serious concern to the nation's health, and

Whereas, The use of the bedside worker trained to perform many routine tasks in the care of bed patients in hospitals has been proved by wartime experience in both military and civilian hospitals to be an acceptable expedient to supplement the services of available graduate professional nurses to the advantage of the patients' care, and

Whereas, The New York State Board of Nurse Examiners, while licensing practical nurses with requisite training and qualifications, prohibits the training of practical nurses in any hospital maintaining a school for the training of graduate professional nurses, and

Whereas, The best facilities for the training of those concerned with the care of the sick are generally to be found in those hospitals with approved schools of nursing, and

Whereas, Short orientation courses for so called attendants, or nurse s aides, do not appear to offer a satisfactory solution to the problem of better and more adequate bedside care, and

Whereas, The Medical Society of the State of New York has gone on record as endorsing an extension of the training program for practical nurses, in addition to its continued efforts to increase the available supply of registered professional nurses, and

Whereas, The Medical Society of the State of New York, in cooperation with the State Board of Nurse Examiners and the New York State Hospital Association, seeks liberalization of the interpretation of existing laws so as to permit the training of practical nurses in all hospitals now conducting training schools for registered professional nurses, and

Whereas, The Medical Society of the State of New York urges the establishment of training programs for practical nurses in approved hospitals not at present conducting a nurse training program of any sort; therefore be it

Resolved, That the Board of Trustees of the American Medical Association is hereby requested to take action urging similar steps on a nationwide basis, in collaboration with other bodies concerned with the training of nurses

Resolutions on Medical Care of Dependents of Service Men

Dr. Raymond L. Zech, Washington, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, The objectives of the Emergency Maternal and Infant Care program have been accomplished through the cooperation of civilian doctors, and

Whereas, The Medical Departments of the armed forces now are adequately staffed to care for the dependents of service men, therefore be it

Resolved, That in the interests of economy during peacetime the medical care of dependents of service men might properly be made a function of the Medical Departments of the armed services; and be it further

Resolved, That the American Medical Association direct the attention of the proper committees in Congress to this matter, with the object of transferring these functions to the medical deparments of the armed forces

Resolutions on Allotment of Residencies

Dr. Ivan Fawcett, West Virginia, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

Whereas, There is great need for more general practitioners of medicine especially in the smaller communities of this country; and,

Whereas, General practice in such areas tends to develop self reliance and a well rounded knowledge of the entire field of medicine, thereby giving candidates for specialization a broad professional educational basis, therefore be it

Resolved, By the House of Delegates of the West Virginia State Medical Association, that we approve the principle of alloting one half the specialty residencies to applicants who have had five years' experience in general practice in smaller communities, say under 10,000 population, and allowing due time credit, say two years, for such general practice, and be it further

Resolved, That our delegates to the American Medical Association be instructed to present these resolutions to the House of Delegates of the American Medical Association at the Atlantic City session with the request that they be approved and forwarded to the various specialty boards for consideration

Supplementary Report of Board of Trustees

WORLD MEDICAL ASSOCIATION

Dr. R. L. Sensenich, Chairman, presented the following supplementary report, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

The House of Delegates has been informed of the preliminary meetings preparatory to the formation of a World Medical Association and this matter is included in the report of the Board of Trustees Dr E L Henderson and Dr. Louis H Bauer of the Board of Trustees represented the American Medical Association at a preliminary organization meeting in London Dr. Henderson and Dr. Bauer, together with Dr. Ernest E Irons as an observer, have been designated to represent the Association in a meeting to be held later in the year. This would seem to be an opportunity and responsibility of the American Medical Association to assist in the development of a world medical front in meeting problems as they develop in the activities of the World Health Organization and in the divisions of the United Nations.

PAN AMERICAN MEDICAL FEDERATION

A Pan American Medical Federation is in process of development and Dr. Harrison H Shoulders, Dr. Charles Gordon Heyd and Dr Austin E. Smith represented the American Medical Association at a preliminary meeting at Havana last autumn Pan American nations are looking to the United States and Canada for leadership in medical progress, and this would seem to be a helpful measure in the promotion of higher standards of medical care in the Western Hemisphere

COMMITTEE ON LIAISON WITH VETERANS ADMINISTRATION

The Board of Trustees has appointed a committee to serve as a means of liaison with the Veterans Administration in consideration of frequently developing problems of veterans' medical care Dr. Herbert H. Bauckus, Buffalo, Dr. Edgar P. McNamee, Cleveland, Dr. H. H. Shoulders, Nashville, Tenn, Dr R L Sensenich, South Bend, Ind, and Dr. George F.

Lull, Chicago, were named to represent the Association. This committee was appointed by the Board of Trustees because of the apparent emergencies so frequently developing.

RESOLUTION ON INSURANCE AGAINST LOSS OF WAGES DURING SICKNESS

A resolution introduced by Dr. Alex F. Burgess, Rhode Island, at San Francisco concerning loss of wages during sickness and the report of the reference committee were referred to the Council on Medical Service. That Council, however, is at a loss to interpret the meaning of the report of the reference committee, and the Board of Trustees referred this question to the Judicial Council for interpretation. The Judicial Council has now clarified the meaning of the reference committee's report, and the matter has been referred to the Council on Medical Service for study and report to the Board of Trustees.

WOMAN'S AUXILIARY

The office of the Woman's Auxiliary of the American Medical Association is now located in the headquarters of the American Medical Association. This should make possible a far more effective coordination of the activities of the Auxiliary and the Association.

INCREASE IN COSTS OF OPERATION

The costs of operation of the Association have increased very greatly in the last several years. The activities of the Association have been greatly expanded. Operating costs in employment of personnel to carry on these activities are the major items in those increases. However, material costs, especially paper, have increased very greatly. Proposed legislation to increase United States postal rates if enacted would add approximately $89,000 to the annual costs of the Association. The income from the Association is derived from advertising and JOURNAL subscriptions. As the $8 annual subscription price of THE JOURNAL is only a minor fraction of the cost of the production of THE JOURNAL, it is evident that the activities of the Association are dependent on the advertising. The Board of Trustees found it necessary to make some reduction in the operating budgets in order to avoid going into reserve set up for the safety of already established activities of the Association. This information is to assist the House in the consideration of proposals of new activities that may be presented to the House.

Respectfully submitted,

R. L. SENSENICH, Chairman.
ERNEST E. IRONS, Secretary.
DWIGHT H. MURRAY.
WILLIAM F. BRAASCH.
LOUIS H. BAUER.
ELMER L. HENDERSON.
JOHN H. FITZGIBBON.
JAMES R. MILLER.
CHARLES W. ROBERTS.

Report of Reference Committee on Legislation and Public Relations

Dr. Thomas P. Murdock, Chairman, presented the following report, which on motions of Dr. Murdock, duly seconded and carried, was adopted section by section and as a whole:

1. Resolutions on Medical Care of Veterans: Your reference committee has reviewed the resolutions presented by the Missouri State Medical Association on Public Law No. 293, which permits the employment of unqualified professional personnel in the Veterans Administration.

Your committee is in agreement with these resolutions in principle and submits the following substitute resolutions:

Resolved, That the House of Delegates of the American Medical Association go on record in its disapproval of the employment of unqualified personnel in the Veterans Administration; and be it further

Resolved, That it recommends the repeal of this provision in Public Law No. 293.

2. Report of Council on Medical Service dealing with legislative matters: That portion of the report of the Council on Medical Service dealing with legislative matters was reviewed by the Reference Committee on Legislation and Public Relations.

Your committee endorses heartily the activities of the Council on Medical Service and calls to your attention the enormous amount of work done by this council.

Your committee also feels that great praise is due Dr. Joseph S. Lawrence and the Washington staff for their constant vigilance in our behalf.

3. Resolutions on Hospitals Entering into the Practice of Medicine: Your reference committee has given careful consideration to the resolutions presented to the House of Delegates by the West Virginia State Medical Association and presents the following resolutions in replacement:

Resolved, That the House of Delegates of the American Medical Association is in complete agreement with the recommendations of the West Virginia State Medical Association in its opposition to the encroachment by hospitals and other organizations on the private practice of *medicine; and be it further*

Resolved, That all fees for medical services be set by and collected by or for doctors of medicine rendering this service, and that all policies and practices involving medical services be approved by the medical board or medical staff before being put into effect; and be it further

Resolved, That the Council on Medical Education and Hospitals recommend *strongly that all hospitals conform to these resolutions;* and be it further

Resolved, That the House of Delegates of the American Medical Association go on record as strongly disapproving this practice of encroachment, and that notice of this action be sent to the American, Protestant and Catholic hospital associations and to Blue Cross organizations.

Respectfully submitted,

THOMAS P. MURDOCK, Chairman.
THOMAS A. MCGOLDRICK.
WILLIAM M. SKIPP.
LLOYD NOLAND.
FORREST J. PINKERTON.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. H. B. Everett, Tennessee, and carried, the House recessed at 12 m. to reconvene at 2:15 p. m.

Tuesday Afternoon

The House reconvened at 3:15 p. m., with the Speaker, Dr. R. W. Fouts, presiding.

During the luncheon for the delegates, the members of the House had the pleasure of hearing an address by Hon. John N. Brown, Assistant Secretary of the Navy for Air, and one by Hon. Robert P. Patterson, Secretary of War.

Introduction of Invited Foreign Guests

Dr. Morris Fishbein, Editor of THE JOURNAL, introduced several foreign guests.

Dr. George Constam, representative of the government of Switzerland and the Swiss Medical Federation, who later addressed the House, was first introduced.

Dr. Fishbein then presented Dr. Manuel Guevera Oropesa, a representative of the Mexican National Medical Association, and Dr. Francisco de P. Miranda, Mexico City, one of the leading internists of the world, the latter of whom spoke as follows:

Gentlemen, I bring to you the greetings of the Secretary of Public Health and Welfare of Mexico and I am also representing the National Academy of Medicine.

Dr. Fishbein then presented Dr. Gonzalo Esguerra Gomez, Bogota, Colombia, who presented a statement printed in Spanish.

Dr. Szeming Sze, official delegate from the Chinese Medical Association and the Republic of China, was then presented and spoke as follows:

Mr. Speaker, on behalf of the Chinese Medical Association I have the honor to bring to you not only fraternal greetings but also our most cordial congratulations. According to Chinese custom on special birthdays, like a hundredth birthday, we present a scroll with an appropriate theme and I have been requested to bring to you today an appropriate scroll. It is written in Chinese. I think Dr. Fishbein may have difficulty in translating it. I will just take one minute to translate it for him. A Chinese painting, a painting of a pine tree, which in China is emblematic of longevity, and the inscription reads "To the American Medical Association on the occasion of its hundredth anniversary, the Chinese Medical Association respectfully presents this, June 1947, at Atlantic City." There is a verse from our classics, and the thought of that might be translated "Long life to the profession which gives long life to mankind and humanity."

Dr. Fishbein then presented Dr. José Valls, a representative of the Argentine Medical Association, widely known throughout the world as a great contributor to orthopedic surgery, who addressed the House as follows:

Gentlemen, I am very pleased to bring to you the greetings of the Argentine Medical Association, of which it is my privilege now to be the president, and also of the University of Buenos Aires, to which I belong.

Dr. Harald Bjelke, a delegate of Norway and the Norwegian Medical Association, was then presented and read the following address:

While traveling in the United States on a Rockefeller Foundation grant I was informed that the Norwegian government had been invited to participate in the Centennial Celebration of the American Medical Association, and that in a cabinet meeting of March 27 I had been appointed to represent the government and bring you its heartiest greetings. I have also been informed by the executive board of the Norwegian Medical Association that Dr. Thorstein Guthe, who was to have been their representative, unfortunately is unable to be here, and the board has asked me to greet you on behalf of the Norwegian medical profession and to thank you for all assistance accorded Norwegian physicians who have come to study in the United States, and also to thank you for all that American medical science has done for the benefit of peoples' health also in Norway.

After having spent some months here and seen with my own eyes the high level of medical science and research in this great and rich country with its forty-eight states, I am very happy indeed to be here and to convey to you their congratulations. On behalf of the Norwegian government and the Norwegian Medical Association I express the wish that the progress which medical research and work have made in this country in the past hundred years may continue and, with the opportunities which you have here, may become still greater—for the benefit of all humanity everywhere—not only in medicine but also morally, so that the peoples of the world some day, in the not too distant future, can live together in peace and happiness, both as individuals and as states, peoples, and races.

Dr. Gyula Bencze, after being presented to the House by Dr. Fishbein, read the following address:

Mr. Speaker, Members of the House of Delegates, Ladies and Gentlemen:

As delegate from the faculty of medicine of the Pazmany Peter University and the Medical Association of Budapest, I have the duty and pleasure to thank you for your kind invitation and to bring you their best wishes. Your centenary affords the first opportunity to reestablish the scientific contacts broken by the war.

International collaboration has been very fruitful in the past. We are happy to be able once more to join in the common effort and be in a position to benefit from the great achievements of American science, which has earned the admiration and thankfulness of the whole world with its progress even during the years of general destruction of the past war.

Next year the Budapest Medical Association will celebrate a memorial for the great Hungarian Philip Semmelweis, "the savior of mothers." It is therefore my privilege and pleasure to extend to you the invitation of the Medical Association of Budapest, and may I express the hope that your delegates will participate in the Budapest meetings. Thank you.

Dr. Fishbein announced that the next speaker came as a representative of two important organizations, the Royal Egyptian Medical Association and at the same time the Saudi Arabian government, Dr. A. Z. Abushady. Dr. Abushady spoke as follows:

Mr. Chairman, Fellow Colleagues:

It is both my pleasure and my honor to convey to you the greetings of the Saudi Arabian government and of the Royal Egyptian Association. Perhaps a number of you are aware that one of the oldest model colleges of medicine was created in Cairo over a century ago and thanks to the collaboration of French scholars and later of British scholars and medical men we managed not only to develop in the University of Cairo the famous medical college, but also the College of Medicine at Alexandria, where I was honored by holding the professorship of bacteriology for some time. I am sure in extending these greetings to you in behalf of the Saudi Arabian government, which is developing many model institutions for the advancement of public health, and of the Royal Egyptian Medical Association, it would be appreciated by my government and association if I should extend also to you a hearty welcome to visit these lands and to see these parts of the globe where appreciation of Western democracy and Western sciences and particularly medical science is advancing in a practical way, as shown by the hundreds of students that are now studying medicine in Britain and in America and are unofficial ambassadors of friendship between both countries.

Dr. Fishbein recalled Dr. George Constam of Switzerland, who desired to present a special medal developed for this occasion. Dr. Constam addressed the House as follows:

Mr. Chairman, ladies and gentlemen, the Federation of Swiss Physicians charges me to express to you the most cordial greetings and sincerest congratulations. The Constitution of the United States of America serves as a model for the one on which the actual political structure of Switzerland is based, and this proves that the two countries in spite of the great difference in size and population have many fundamental ideas in common. Therefore, a great number of problems which the American Medical Association had to solve or will have to face were, are and will be of importance to the Swiss Medical Association.

For many years we have followed closely and with the greatest interest the development of medicine, its basic sciences and technic in this country, and we have admired the important and often decisive role the American Medical Association has played in leading your country to the undisputed first rank in universal medicine.

The Federation of Swiss Physicians is very happy to have today an opportunity to express to you its admiration for what your Association has accomplished during the last hundred years for the benefit not only of your and of our country but of the whole world.

As a modest sign of our gratitude, I have the honor to present you this little medal and to express to you the hopes that you will continue your so very successful activities for the benefit of mankind.

Dr. Morris Fishbein, Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, stated that the Board of Trustees of the Association had in mind preparation of a permanent special place for these trophies and tokens in the headquarters office, in the reception room, with suitable labels, so that they will be available at all times to the entire membership of the Association. He then presented the representative of the National Medical Association of Panama, Dr. J. S. Vallarino, who spoke as follows:

Mr. Chairman and delegates, my colleagues and friends, I want to extend our greetings and the heartiest best wishes for the continued success of the American Medical Association. It was through the great efforts of one of the great men of the past that the sanitation of the Panama Canal Zone was carried forward and enabled the construction of the Canal, and I want to pay great tribute here to our very beloved William Crawford Gorgas. Thank you.

The Speaker announced that there would be opportunity for the introduction of new resolutions, if any, and for the reception of committee reports, if any, either before or after the Executive Session.

Communication on Pan American Organization

The physicians from Cuba were again presented and, with the permission of the House, Dr. Felix Hurtado, delegate from the Pan American Congress, was granted ten to fifteen minutes to present to the House a problem in which he was interested, which he did as follows:

The Colegio Medico Nacional de Cuba (Cuban Medical Association) called the first Pan American Medical-Social Congress, which met in Havana in December 1946.

In this congress have been represented all the medical organizations of the continent, including the American Medical Association, which sent three men under the leadership of Dr. Shoulders, who can inform you about their impressions of this event.

We can consider the reunion of Havana as the first step in the consolidation of a big Pan American organization of physicians.

We believe that this is a desirable opportunity to consider the importance of a fraternal union among all medical doctors in favor of their own interest and also in favor of a great development of medical progress.

It is true that medical development is not similar in all the countries of the continent because the social and economic development of all countries on the American continent have not reached the same level.

We know very well that these particular circumstances do not permit the establishment of a general system and similar methods for the whole continent.

For these reasons the first and principal point clarified by the first Pan American Medical-Social Congress and the Pan American Medical Confederation is the statement that each country will conserve its particular internal structure in accordance with its medical organization, with entire freedom to handle its own domestic affairs.

Therefore on these political principles and philosophic basis these organizations would be conducted according to their own ideas and be entirely independent of the general rules for the establishment of the Pan American Medical Confederation.

The Pan American Medical Confederation would be an international bureau for the establishment of a real link among all the medical groups of the continent. This is a simple interpretation of that historic document called the "Chart of Havana," accepted by all the countries represented in the first Pan American Medical-Social Congress. In order to facilitate the administration and the study of the medical affairs of the continent, the Pan American Medical Confederation has divided the continent into five regions:

Northern Zone: Canada and the United States. Seat: American Medical Association, Chicago.

Central American Zone: Mexico, Honduras, Guatemala, Nicaragua, El Salvador, Costa Rica and Panama. Seat: Medical Federation of Guatemala (Guatemala).

Caribbean Zone: Cuba, Haiti, Santo Domingo, Puerto Rico, Colombia and Venezuela. Seat: Venezuelan Medical Federation (Caracas).

South Atlantic Zone: Brazil, Argentina, Paraguay, Uruguay. Seat: Medical College and Syndicate of Uruguay (Montevideo).

South Pacific Zone: Chile, Peru, Ecuador and Bolivia. Seat: Medical Association of Chile (Santiago).

The present state of this organization and the entrance of the countries is, as follows:

Central American Zone: All the countries: Mexico, Honduras, Guatemala, Nicaragua, El Salvador, Costa Rica and Panama.

Caribbean Zone: Cuba, Santo Domingo, Puerto Rico, Colombia and Venezuela. Only lacking is the entrance of Haiti.

South Atlantic Zone: Uruguay and Argentina. The Argentine Medical Association has made its entrance conditional on the scientific purposes of the confederation because this is the only way its by-laws allow it to be associated with other institutions.

As to the remaining countries of the zone (Brazil and Paraguay) we maintain contact with the delegate of the National Academy of Medicine of Rio de Janeiro, the near entrance of which we are expecting. We are also in contact with our Paraguayan colleagues, and we are expecting their entrance into the organization.

South Pacific Zone: Chile, Peru and Ecuador. Only Bolivia has not entered, but we are already in contact with the Bolivian medical institutions and personnel and expect them to enter.

The Pan American Medical Confederation is constituted by the medical organizations that in each country represent and group a majority of the professional physicians, such as the American Medical Association, the Medical Association of Chile, the Peruvian Medical Association, the Venezuelan Medical Federation, and some, as the National Medical College of Cuba that, by virtue of the national laws, group all the physicians, since it is a necessary prerequisite to the practice of medicine in Cuba to be inscribed in the National Medical College.

All those institutions are wholly autonomous in the execution of their functions, having only to be grouped in each zone and appointing a delegate from each country, constituting with the other three secretaries appointed by the country seat of the zone what is called the Zonal Secretariat.

To our members' best understanding each Zonal Secretariat (constituted of the three secretaries of the country seat and a delegate for each of the countries that forms it) meets from time to time with the remaining Zonal Secretariats and Havana's Secretariat in a body called the General Council, which will draw up the basis and programs of a general meeting, the Pan American Medical-Social Congress, which meets every other year in a different country of our continent.

The Secretariat of Havana, then, is a coordinating group of the relationships of the zones among themselves, those of the General Council of the Confederation and the Pan American Medical-Social Congress.

As a result of an extensive and deep study of the medical situation in the continent, the Executive Board of the Pan American Medical Confederation has considered two sides for interpretation of the medical standards in the continent. On one side is included all the matters in relation to scientific development.

In this sense information is very important about medical education: (*a*) medical school standards; (*b*) special information about standards for students, particularly in the premedical aspects; (*c*) hospital services: department of social assistance (social work), bad teaching, center of research: foundation, laboratories, institutes (one example of each of these three types: Rockefeller Foundation, National Laboratory of Chile, Institute of Finlay, Havana); (*d*) academies: academy of medical science, medical societies; local branches of international corporations; (*e*) medical congress: staff meetings, annual meetings of national congress, international meetings or congress; (*f*) international center, like "Instituto de Proteccion a la Infancia," Montevideo, or Pan American Sanitary Bureau.

The other side is called the social aspect, which includes different topics: (*a*) medical institutions: societies or associations, free, independent, private, regular or official and compulsory; (*b*) trade unions (medical organizations organized under rules similar to those of labor unions); (*c*) syndicates. Philosophical orientation of the medical groups: (*a*) individualist doctrines; (*b*) collectivist doctrines. 3. Particular aspect of social security: (*a*) insurance companies; (*b*) mutual societies; (*c*) compulsory social security; (*d*) the new concept of social security particularly adapted to each country; (*e*) social security in the United States.

The general policy of the Pan American Medical Confederation would be to develop a basic plan of education and to extend all different kinds of advices in order to facilitate the most rapid development particularly in those countries in which the standard is yet very low.

We consider that there will not be any trouble for the American Medical Association particularly as this institution does not interfere with any domestic action in any medical group in the continent.

The Pan American Medical Confederation will offer a very important support to the national local organization and in many times could offer its friendly intervention to promote always the most favorable solution among the medical groups.

Finally, in the name of the Pan American Medical Confederation we request the Executive Board of the American

Medical Association to make a motion before the corresponding body in order of your taking action for the incorporation to the Pan American Medical Confederation as representative of the medical association of the United States.

In the official declaration of the incorporation of the American Medical Association with the Pan American Medical Confederation any particular reservation could be made, utilizing the diplomatic system of the International Convention.

The incorporation of the American Medical Association would make the Pan American Medical Confederation very happy and the Confederation hopes that you will appoint some outstanding representative physician of the United States for the position of head of the Region (United States and Canada), always having in mind that in the meeting of the Secretaryship of the Pan American Medical Confederation this member from the United States will be chosen as a leader of the scientific advisers.

This matter was referred to the Reference Committee on Medical Education.

It was moved by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, that the House go into Executive Session, and the motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried after discussion.

Dr. Herbert P. Ramsey, District of Columbia, moved that, as in recent years, the Executive Sessions should include officers of state medical associations, members of the American Medical Association, executive secretaries of state medical societies and editors of state medical journals, and the motion was seconded by several and, after discussion, was lost.

The House convened in Executive Session at 4:15 p. m. and resumed regular session at 5:15 p. m.

Resolution on Establishment of Committee on Public Relations

In Executive Session Dr. Allen H. Bunce, Georgia, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

Resolved, That a Committee on Public Relations be established in the headquarters office, composed of the Secretry and General Manager, the resident Trustee and the Editor of The Journal, which shall have charge of the public relations of the American Medical Association under the general direction of the Board of Trustees.

Report from Hawaii

There was also presented in Executive Session a report from Hawaii, which was referred to the Reference Committee on Legislation and Public Relations.

Resolution on Limitation of Tenure of Office of Delegates

Dr. Theodore H. Harwood, Vermont, presented the following resolution, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws, which was requested to consult with the Judicial Council:

Whereas, Constantly changing social and economic conditions require that those who establish the policies of the American Medical Association be familiar with needs of the active generation and be capable of rapid adjustments and decisions; and

Whereas, It has been amply demonstrated in the recent war that young physicians are fully capable of undertaking great responsibility; and

Whereas, The American Medical Association and many of its constituent state associations have already recognized both this principle and the value of constant injection of new ideas in their higher offices by limiting tenure in the Board of Trustees and in the Councils; now therefore be it

Resolved, By the House of Delegates of the American Medical Association that the principle of limitation of tenure of office be extended to members of this House of Delegates and that the Committee to Study Revision of the Constitution and By-Laws be and is hereby instructed to prepare suitable amendments to implement this policy.

Supplementary Report of Council on Medical Service

Dr. James R. McVay, Vice Chairman, presented the following supplementary report of the Council on Medical Service, which was referred to the Reference Committee on Miscellaneous Business:

PLANNING FOR THE CHRONICALLY ILL

Early this spring the Board of Trustees referred a statement on "Planning for the Chronically Ill" to the Council on Medical Service with the suggestion that the Council select an Advisory Committee to assist Dr. James R. Miller in studying this statement.

The Council submitted four names to the Board of Trustees to act as an Advisory Committee in assisting Dr. Miller. This committee was approved by the Board of Trustees.

The statement "Planning for the Chronically Ill" was prepared as a joint statement of and to be released by the American Hospital Association, American Public Health Association, American Public Welfare Association and American Medical Association. Primarily, it is a recognition of the problems of chronic illness and an attempt to provide a useful guide and stimulus to those interested in planning for the chronically ill.

The Council on Medical Service commends Dr. Miller and others responsible for drawing up the statement and suggests to the House of Delegates that it be approved as a preliminary statement concerning the problems of the chronically ill, and that Dr. James R. Miller and the Advisory Committee be authorized to proceed further in investigating and evaluating these problems.

Respectfully submitted,

E. J. McCormick, Chairman.
R. L. Zech.
James R. McVay.
A. W. Adson.
Walter B. Martin.
Thomas A. McGoldrick.
Roger I. Lee.
H. H. Shoulders.
Louis H. Bauer.
George F. Lull.
Thomas A. Hendricks, Secretary.

Dr. Roy B. Henline, Section on Urology, moved that the House recess until 2 o'clock Wednesday afternoon, June 11. The motion was seconded by several and carried, and the meeting recessed at 5:45 p. m. to reconvene at 2 p. m., Wednesday, June 11.

Third Meeting—Wednesday, June 11

The House reconvened at 2:15 p. m., Wednesday, June 11, 1947, with the Speaker, Dr. R. W. Fouts, presiding.

Introduction of Invited Foreign Guests

Dr. Morris Fishbein, Editor of The Journal, presented Dr. Tauno Putkonen, representing the government of Finland, who addressed the House (a copy of this address is not at present available).

Dr. Fishbein showed the special document from the Finnish Medical Association and then presented Dr. Rolf Bergman, representing the Swedish government, and Dr. Sven Forssman, a noted authority on industrial health, representing the Swedish Medical Association.

Hon. T. Lindsay, representing the United Kingdom, was introduced and spoke as follows:

I think I should just mention that I am exhibit A, I am not a doctor, I am a specimen of the bureaucrats to which the British Medical Association is subjected, and we are such good friends that you may ask Dr. Dain and Dr. Charles Hill whether they have any objections to me.

Dr. Morris Fishbein, then presented Dr. José J. Centurion, professor of internal medicine in the University of Havana, Cuba, representing the university, who spoke as follows:

Havana is following with great interest the great meetings you are having here. In the name of the faculty, they send best regards to you all and hope that Cuba, with the university, will be following the United States in all these events.

Dr. E. Torab Mehra, representative of the government of Iran, was then presented and addressed the House as follows:

If you will forgive me, I should like to say that this is a great personal honor and privilege to represent my government and the physicians of Iran before you distinguished gentlemen here. I know that your time is very valuable. I should just like to say a few words concerning the physicians of Iran.

I have been fortunate enough to come to this country and become educated in this country, so I well know what the American Medical Association has done to raise the standard of medical care in this country. I should like to mention to you that from now on the duty of the American Medical Association is more than in this country; it has passed the boundaries and is more or less international. The people of my country look to America at the present time as the leader, and we follow your steps in every respect.

We hope that in the future we shall raise the standard of health in our country, and that will be possible only with your help and assistance. I would just like to suggest several things that you distinguished gentlemen could do for the people of the Near East and Iranians in particular. One would be to open up the doors of your schools to more Iranian students. I have come here and I know how difficult it is to get admitted to American medical schools. Dr. Weiskotten can tell you how much difficulty I had when I went to Syracuse University to stay. Whatever I say to you is right out of my heart, and I mention this fact to you because it is extremely important.

Secondly, because of our foreign exchange, you gentlemen have to put up some kind of scholarship for the working students who come to this country and want to study here so they should not have to spend the time, when they should be studying anatomy, washing dishes and doing other work to use up their time.

I believe that is all that has been in my heart for the past twelve years in this country and I hoped that some time I could stand up before you and tell you, though it may be very inadequate.

Roll Call

A motion was made by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Thomas S. Cullen, Maryland, and carried, that the registration be considered the roll call.

Report of Reference Committee on Credentials

Dr. G. Henry Mundt, chairman, announced that 173 delegates had registered.

Report of Reference Committee on Medical Education

Dr. George W. Kosmak, Chairman, presented the following report, which on motions of Dr. Kosmak, duly seconded and carried, was adopted section by section and as a whole, with the exception of the report of the reference committee on the Resolution on the Nursing Shortage, which was laid on the table on motion of Dr. James R. Reuling, New York, seconded by several and carried:

1. Report of Council on Medical Education and Hospitals: Your reference committee has studied the report of the Council on Medical Education and Hospitals as published in the Handbook and recommends also that every member of the House study this report carefully. Your committee commends the Council for the complete and conscientious report on the problems relating to the reconversion of medical education from a wartime to a peacetime basis and wishes especially to commend the excellent work in providing opportunities for residency training desired by returning medical officers. It is gratifying also to note that plans are under way by the Council for a comprehensive resurvey of all medical schools and all aspects of medical education, including the financing of medical education, the teaching of medical economics and the social aspects of medicine, of public health, of preventive medicine and of other components of the medical school curriculum.

2. Supplementary Report of Council on Medical Education and Hospitals: The supplementary report of the Council, dealing with hospital staff appointments and with the problem of the general practice of medicine and recommending that sections on general practice be established in hospitals, was referred to the Reference Committee on General Medical Practice except for one portion of the supplementary report dealing with a change in the "Essentials of a Registered Hospital."

Your reference committee recommends that the wording of section 3, paragraph 6, dealing with the staff organization of a hospital be changed to read as follows: "6. Staff sections, such as medicine, obstetrics, surgery, general practice, etc., should be organized as may seem wise."

3. Supplementary Report of the Council on Medical Education and Hospitals: The supplementary report of the Council revising the "Essentials of Approved Residencies and Fellowships" is recommended for approval.

4. Resolution on Need of a Greater Income for Medical Schools: Your reference committee finds that the Council is planning to include a study of the financing of medical education in its survey of medical schools.

Your committee recommends that the resolution be referred to the Council on Medical Education and Hospitals for study in connection with the resurvey of medical schools.

5. Resolutions on Indoctrinating Medical Students with Philosophy and Ethics of Profession: Your committee finds that the Bureau of Medical Economic Research, in collaboration with the Council on Medical Education and Hospitals, is surveying the instruction of medical students in this field and will prepare a syllabus with pertinent information and reading references in the general field of medical economics and the social aspects of medicine for use in the instruction of medical students and interns.

Your committee recommends that these resolutions be referred to the Council on Medical Education and Hospitals as a guide to efforts in this direction.

6. Resolutions on Hospital-Specialty Board Relationships: Your reference committee wishes to call attention to the supplementary report which the Council has made to this house regarding hospital staff appointments as related to specialty certification. In that report the Council stressed the principle that hospital staff appointments should be made on the basis of ability and merit and not on specialty board certification or membership in special societies.

Your reference committee recommends that these resolutions be referred to the Council on Medical Education and Hospitals.

7. Resolutions on Teaching of Medical Economics in Medical Schools: Your committee finds that the Bureau of Medical Economic Research in collaboration with the Council on Medical Education and Hospitals is surveying the instruction of medical students in this field and will prepare a syllabus with pertinent information and reading references in the general field of medical economics and the social aspects of medicine for use in the instruction of medical students and interns.

Your committee recommends that these resolutions be referred to the Council on Medical Education and Hospitals as a guide to efforts in this direction.

8. Communication on Pan American Organization: Your reference committee recommends that this communication, referring to the desirability of establishing a Pan American organization of physicians, be referred to the Board of Trustees for appropriate action.

9. Resolutions on Training of Medical Students to Administer Programs of Health and Medical Services in Schools and in Industry: Your committee recommends adoption of these resolutions with the elimination of the last paragraph.

10. Resolution on Nursing Shortage: Your reference committee recommends adoption of this resolution, urging the establishment of training programs for practical nurses.

Respectfully submitted,

GEORGE W. KOSMAK, Chairman.
JOSEPH D. MCCARTHY.
THOMAS S. CULLEN.
WILLIAM D. STOVALL.
A. W. ADSON.

Report of Reference Committee on Legislation and Public Relations

Dr. Thomas P. Murdock, Chairman, presented the following report, which, on motions of Dr. Murdock, duly seconded and carried after discussion, was adopted section by section and as a whole with the exception of the report of the committee dealing with the Resolution on S. 140, with the Resolution on Effective Program of Public Relations and with the Resolution on Establishment of Committee on Public Relations, which were rereferred to the reference committee:

1. Resolutions on Hospital Competition with Private Practice: Your reference committee has carefully considered these resolutions and recommends that no action be taken because these resolutions in general were covered by a more comprehensive resolution submitted by the West Virginia delegate and approved by this House of Delegates.

2. Resolution Requesting Discontinuance of Notorization of Declaration of Narcotics in Hand to Accompanying Renewal of Stamps: Your reference committee recommends approval of this resolution.

3. Resolution on Medical Care of Dependents of Service Men: Your reference committee recommends disapproval of these resolutions.

4. Resolutions on S. 140: Your reference committee recommends the addition to these resolutions as follows: "and be it further *Resolved*, That the House of Delegates go on record expressing its disapproval of any bill combining health, education and welfare."

5. Resolution on Group Practice: Your reference committee has given careful consideration to this resolution and calls to your attention that the Judicial Council included the question of group practice in its report and that a study is now under way by the Bureau of Medical Economic Research.

Therefore, your committee presents the following substitute resolutions:

Resolved, That the House of Delegates go on record approving a study of the question of group practice; and be it further

Resolved, That this matter be referred to the Board of Trustees with the suggestion that it be referred to the Bureau of Medical Economic Research, the Judicial Council, the Council on Medical Service and the Bureau of Legal Medicine and Legislation.

6. Report of Judicial Council: Your reference committee has carefully reviewed the report of the Judicial Council as it appeared in the Handbook, which covered the activities of the Council since the midwinter meeting in December.

Two formal meetings were held and the usual routine work was reported. This work included consideration of questionable eligibility of applicants for Fellowship, recommendation of candidates for Associate Fellowship and many decisions on the ethics of practice.

The Council reported many requests for information or approval by ophthalmologists.

The Council report includes the report of Dr. A. C. Ivy as a representative of the government of the United States in which the war crimes of a medical nature were reviewed.

The report explains the duties of the Council as distinguished from the duties of the House of Delegates and state associations. Included in the report also are studies of group practice and voluntary insurance plans.

It can be said that the Council has had a busy year and has done its work well.

7. Resolutions on Effective Program of Public Relations and Resolution on Establishment of Committee on Public Relations: Your reference committee recommends adoption of the following resolutions as a substitute for those introduced:

Whereas, The House of Delegates has authorized and endorsed an effective program of public relations for the American medical profession; and

Whereas, The American Medical Association is the only organization which is qualified to speak with authority for American medicine; be it therefore

Resolved, That a Committee on Public Relations be established in the headquarters office composed of the Secretary and General Manager, the resident Trustee and the Editor of The Journal, which shall have charge of the public relations of the American Medical Association under the general direction of the Board of Trustees; and be it further

Resolved, That if the Board of Trustees is convinced that the Association cannot afford to carry out a public relations program, Fellowship dues be increased to $10 per annum.

8. Report from Hawaii: Your reference committee has reviewed the report from and has heard the delegate of the Hawaii Territorial Medical Association. This report had to do with the presentation of a bill in the Territorial Legislature in an attempt to socialize medicine. This resulted in the unification of medical forces. A press, radio and letter campaign was conducted which was successful and the bill died in committee. The delegate brought out that the National Physicians Committee was of great help in the defeat of the bill. The delegate was of the opinion that the bill was inspired and promulgated by Communists.

As a result of this report and the testimony of the delegate, your reference committee presents the following resolutions: be it

Resolved, That the House of Delegates of the American Medical Association congratulate the Hawaii Territorial Medical Association; and be it further

Resolved, That the House of Delegates recognize that a similar situation exists on this continent; and be it further

Resolved, That the House of Delegates of the American Medical Association continue its eternal vigilance and its fight against the forces which are trying to destroy the medical way of life by attacking the "soft underbelly" of the American people—American medicine.

Respectfully submitted,

Thomas P. Murdock, Chairman
Thomas A. McGoldrick.
William M. Skipp.
Lloyd Noland.
Forrest J. Pinkerton.

Report of Reference Committee on Hygiene and Public Health

Dr. Walter E. Vest, Chairman, presented a report, which as amended reads:

1. Report of Committee on Rural Medical Service: Your Reference Committee on Hygiene and Public Health met June 9, immediately following adjournment of the House, and considered the report of the Committee on Rural Medical Service. Your committee feels that the highest commendation is due that committee for the work it has accomplished thus far. Obviously adequate rural medical care is, in many areas, an unsolved problem. Your committee recommends that committees on rural medical service should be set up in those state medical associations not now having them and suggests that the headquarters office should urge on all the state associations the necessity for adequate support of these committees. The development of adequate medical care in much of rural America will of necessity be a long and difficult task and will require time, patience and persistence.

Your committee believes that the development of rural health councils is distinctly in order and that such councils should be actively participated in by the practicing physicians and essentially guided by them. Likewise your committee approves news releases pertaining to health to such rural health councils and farm publications as may from time to time seem pertinent and recommends also that leaflets on preventive medicine and rural medical service issued by the American Medical Association should be distributed to these organizations. Your committee further urges on the Board of Trustees adequate financial support of the Committee on Rural Medical Service.

2. Resolution on National Health Policy: Your committee considered also the resolution which is apparently the plan now operating in Monmouth County, New Jersey.

Your committee approves the resolution in general and recommends that principles 1 and 2 be adopted as presented. However, it is the opinion of your committee that principle 3 as submitted might be at times embarrassing. Hence it is its recommendation that this principle be rewritten as follows:

"3. Each component society invites and welcomes the active participation in its scientific programs by the qualified medical personnel of the appropriate health and welfare agencies and, under suitable circumstances, of the nonmedical personnel as well." Approval of the remaining principles as set forth in the resolution is recommended except that your committee recommends the clarification of 7 by insertion of the word "economically" before the word "suitable" so that this principle will read:

"7. The health and welfare agencies will protect the private practitioner and family doctor by discouraging treatment in preventive clinics by returning to the family doctors any cases not economically suitable for examination or care at the health or welfare agency."

Respectfully submitted,

Walter E. Vest, Chairman.
James P. Wall.
Walter P. Anderton.
Leonce J. Kosminsky.
James A. Crabtree.

The first section of the report of the reference committee was adopted on motion of Dr. Vest, seconded by Dr. C. F. Strosnider, North Carolina, and carried after a motion by Dr. F. S. Crockett, Indiana, seconded by several, to include the words "farm publications" in connection with news releases was carried.

Dr. Vest moved adoption of the second section of the report of the reference committee, referring to the Resolution on National Health Policy, and the motion was seconded by several. After discussion and suggested amendments, this matter was rereferred to the reference committee on motion of Dr. E. S. Hamilton, Illinois, seconded by Dr. J. Stanley Kenney, New York, and carried.

On motion of Dr. Vest, seconded by several and carried, the report of the reference committee was adopted as a whole with the exception of the second section, which had been rereferred to the committee.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. B. E. Pickett Sr., Chairman, presented the following report, which was adopted on motion of Dr. Pickett, seconded by Dr. Robert E. Schlueter, Missouri, and carried:

Resolution on Limitation of Tenure of Office of Delegates: Your reference committee gave due consideration to and discussed with the members of the Judicial Council this resolution and agrees that the resolution may have merit, but it believes that the resolution interferes with the prerogatives of the individual constituent associations and sections of the Scientific Assembly. Therefore your committee recommends disapproval of the resolution.

This report was concurred in by members of the Judicial Council present.

Respectfully submitted,

BRITTON E. PICKETT SR., Chairman.
L. G. CHRISTIAN.
ALLEN H. BUNCE.
HOMER LEE PEARSON JR.
ALFRED S. GIORDANO.

Report of Reference Committee on Reports of Officers

Dr. James R. Reuling, Chairman, presented a report, which as amended reads as follows:

Your reference committee, before taking up the individual reports of the officers, wishes to call the attention of this House of Delegates to the fact that at the opening session of this, our Centennial Celebration, we were privileged to listen to three of the finest addresses that any House has ever heard. Because these addresses contain so many valuable recommendations—suggestions and recommendations that may well set the pattern for the next one hundred years—your committee has had duties far beyond those which usually fall to the Reference Committee on Reports of Officers.

ADDRESS OF THE SPEAKER

The Speaker's address, brief and to the point, reflects his wisdom as Speaker and his judicial mind as a presiding officer. After reviewing the history of the establishment of the position of Speaker of the House and paying tribute to his predecessors, he wisely called attention to a provision in the proposed new By-Laws, regarding the composition of the House during executive sessions. As this House has taken no action on the revision of the Constitution and By-Laws during this session, your reference committee makes the recommendation that only members of the House of Delegates as defined in article 5, section 2, and the general officers as defined in article 6, section 1, of the present Constitution and By-Laws shall be present at an executive session. The House, by a two-thirds majority may, however, invite to be present any individual who in its judgment might assist in the deliberations.

Your reference committee would commend the Speaker for the excellent manner in which he has conducted this important office.

ADDRESS OF THE PRESIDENT

The committee listened with deep interest to President Shoulders and has reread his address with much profit. He points with great clarity to the fact that while changes have taken place in the practice of medicine, the philosophy, the fundamental principles of medicine, do not change.

1. Increasing Availability of Services of General Practitioners: Dr. Shoulders says "It is apparent that the immediate and most urgent needs are concerned with increasing the availability of the services of general practitioners." Your committee believes that the specialty boards have unwittingly contributed to the unwholesome flow of medical students and interns away from general practice and into the specialties and agrees "that the graduate training given in most hospitals approved for the training of interns and residents is designed to satisfy the requirements of specialty boards rather than to meet the needs of general practitioners." Your committee believes that the medical schools also contribute to this state of affairs in that student training is constantly being directed toward the specialties and believes also that the medical schools and the medical boards of all hospitals should pay more attention to the art of the practice of medicine.

Faculties of medical schools and staffs of hospitals should themselves be indoctrinated with the fact that the general practitioner or family doctor is the backbone of the medical profession. They should reiterate to the medical students what Dr. Shoulders has so ably stated concerning the position of the general practitioner in his community and the many rewards for being a family physician.

Dr. Shoulders makes the following recommendations: "That this House of Delegates take action to request the Board of Trustees to appoint and finance a special committee of whatever size is deemed necessary for the purpose of studying all the factors which affect the production and distribution of the type and quality of medical care which the people need and/or desire. In particular, such a committee could (1) define the term 'general practitioner,' or 'general physician,' on a functional basis; (2) determine whether or not there is need for a large increase in the number of medical graduates and, if so, its extent; (3) study the present program of medical education and training, both undergraduate and postgraduate, to determine whether or not the content and administration of the program is properly adjusted to the present day needs of the people; (4) study the possibility and feasibility of utilizing smaller community hospitals in a program for the training of general practitioners and the possibility of approving such institutions for training when a program is properly organized and administered; (5) study the means by which communities in need of additional services may be aided; (6) study such other questions as the committee itself may deem to be necessary at arriving at sound conclusions concerning the entire field of medicine, and (7) propose a long range program designed to overcome present insufficiencies and to meet future needs."

Your reference committee is aware that each of these recommendations is and has been under study by the Council on Medical Education and Hospitals. Such material as has been assembled should be utilized. However, your committee is convinced of the necessity of such a special committee and recommends that a special committee be appointed, the committee to contain a number of general practitioners and to study intensively these seven points and make periodic reports to the House of Delegates.

2. Your committee would direct the attention of every doctor in the United States to the masterful way in which President Shoulders has dramatized the economic changes which have taken place—his similes as to why the cost of medical care seems to have increased should be memorized when he says "When appendicitis was treated largely by the administration of opium pills and the application of poultices to the abdomen, the cost of administering such treatment was low but the resulting mortality was high." . . . "When diabetes was treated by diet and the administration of codiene, the cost of such treatment was low but the mortality was high." He should have added that these individuals and those suffering from many other conditions saved from an early death by the advances of medical science increase the national economy and thereby do not relatively increase the cost of medical care.

ADDRESS OF THE PRESIDENT-ELECT

1. Supplemental Session of House of Delegates to Include Scientific Meeting: The address of President-Elect Bortz contained illuminating discussion and forward looking recommendations. The Association is indeed fortunate in having had Dr. Bortz as Vice President when Dr. Olin West found it imperative to resign.

The first problem which Dr. Bortz presented contained two parts: (1) having a scientific meeting for general practitioners in conjunction with the supplemental session of the House of Delegates and (2) that the supplemental session be rotated to various sections of the country.

Your committee is in hearty accord with these proposals. It forsees in this plan (1) enormous public relations value; (2) raising the general practitioner to the eminence which he deserves in his local community, and (3) educating the headquarters office to local needs, conditions and problems.

Your committee recommends that the supplemental session of the House of Delegates be held in various sections of the country and that there be scientific meetings at these sessions devoted to the general practice of medicine.

2. Affiliation of Medical Students: Your committee agrees with Dr. Bortz in the necessity of securing the closer affiliation of the third and fourth year medical students with the American Medical Association. The committee recommends that the officers of the Association and the appropriate councils carry out his proposals of Affiliate Membership and the reestablishment of a student section in The Journal. Your committee further recommends that the Secretary, in collaboration with the councils and bureaus, prepare an illustrated booklet which will contain a description of the various activities carried on by the American Medical Association and that this booklet be distributed to the members of the Association and to all third and fourth year medical students.

3. Qualified Spokesmen: Your committee recognizes the problem of obtaining a greater number of well qualified speakers. It recommends that the Council on Medical Service assist in the establishment of a speakers' training program in every county medical society. Your committee believes that the Council on Medical Service should bring all of its pamphlets up to date. Recognizing the limitations of physicians in preparing properly coordinated talks, it also recommends that a number of basic speeches be prepared for distribution through the speakers' bureau.

4. The Woman's Auxiliary: Your reference committee concurs in the opinion that the value of the Woman's Auxiliary has been for the most part overlooked in many counties and states. On the other hand, many counties and states know full well the potent public relations value of their auxiliaries. Your committee would have every county and state medical society urge its auxiliary to make use of available material at the headquarters office.

5. The Nursing Crisis: Your committee recognizes this serious situation. It feels that in recent years too much stress has been laid on the technical and scientific preparation of the prospective student nurse rather than on her sympathetic understanding of the problem of patient handling, comfort and ordinary technics of treatment. It recommends that the President appoint a committee of five to be known as the Committee on Nursing Problems. This committee shall investigate the present objectives of the nursing profession, the standards of education, the time involved for training, the various curriculums, the supply of nurses and quality of services rendered, remuneration, participation in the determination of administrative policies and the question of security benefits and to study the training of practical nurses.

6. Medical Preparedness: Your committee feels that this is of the utmost and urgent importance and should be followed up as of today instead of filing away for future disposition.

7. A New Home for the American Medical Association: Dr. Bortz in his address said "The House of Delegates must take under advisement a building program." Your committee after consultation with various individuals believes this matter to be urgent and recommends that the Board of Trustees be empowered to study these needs and take appropriate action.

Respectfully submitted,

James R. Reuling, Chairman.
James Q. Graves.
William H. Halley.
E. N. Roberts.
Deering G. Smith.

It was moved by Dr. Reuling and seconded by several that the first section of the report of the reference committee, dealing with the address of the Speaker concerning attendance at an executive session of the House, be adopted. After proposed amendments, the Chairman accepted the revision of the last sentence so that it reads as it is now contained in the report.

On motion of Dr. Reuling, seconded by Dr. C. F. Strosnider, North Carolina, and carried, the report of the reference committee referring to the address of the President was adopted.

Dr. Reuling moved adoption of the first section of the report of the reference committee dealing with the address of the President-Elect referring to supplemental sessions of the House of Delegates, and the motion was seconded by Dr. Charles R. Rountree, Oklahoma. After discussion, this section of the report of the reference committee was rereferred to it on motion of Dr. C. B. Conklin, District of Columbia, seconded by Dr. Thomas S. Cullen, Maryland, and carried.

It was moved by Dr. Reuling, seconded by Dr. C. F. Strosnider, North Carolina, and carried, that the second section of the report of the reference committee, referring to the address of the President-Elect, be adopted.

The third section of the report of the reference committee, dealing with the address of the President-Elect, was adopted on motion of Dr. Reuling, duly seconded and carried after discussion.

Sections 4 and 5 of the report of the reference committee, referring to the Woman's Auxiliary and the nursing crisis contained in the address of the President-Elect, were adopted as amended on motion of Dr. Reuling, seconded by several and carried after discussion.

The seventh section of the report of the reference committee, relating to a new home for the American Medical Association, referred to in the address of the President-Elect, was adopted on motion of Dr. Reuling, seconded by Dr. Walter E. Vest, West Virginia, and carried.

On motion of Dr. Reuling, seconded by Dr. L. J. Kosminsky, Arkansas, and carried, the report of the reference committee as amended, with the exception of the portion that was rereferred to the reference committee, was adopted as a whole.

Report of Reference Committee on Medical Education

Dr. George W. Kosmak, Chairman, presented the following report:

1. Resolution on the Nursing Shortage. Your reference committee desires to bring up for consideration at this time the Resolution on the Nursing Shortage, which had been laid on the table.

2. Your Reference Committee on Medical Education desires to report its recommendations on two additional resolutions, which, although they were included in the material handed in, were not read in our earlier report to the House of Delegates.

(a) Resolution on Allotment of Residencies: Your reference committee feels that whatever the merits of these resolutions may be, it would not be possible for any organization to enforce the proposal to compel hospitals to reserve one half of their residencies for physicians who have had five years' experience in general practice. Your committee therefore, recommends that these resolutions be not approved.

(b) Resolution on Hospital Standardization: Your reference committee finds that the Council on Medical Education and Hospitals is collaborating with all interested agencies in reviewing hospital standards, so that this resolution is in accord with activities now under way. Your committee recommends that this resolution be referred to the Council on Medical Education and Hospitals for its guidance in its collaborative activities with other accrediting organizations.

On motion of Dr. T. K. Gruber, Michigan, duly seconded and carried, the Resolution on the Nursing Shortage was taken from the table.

Dr. Kosmak moved adoption of the resolution as introduced and the motion was seconded by Dr. Wingate M. Johnson, North Carolina. After discussion and after a motion to rerefer to the committee was lost, another motion to rerefer the matter to the reference committee, made by Dr. T. K. Gruber, Michigan, seconded by Dr. Walter E. Vest, West Virginia, and carried, was adopted and this resolution was rereferred to the reference committee.

Section 2 (*a*) of the report of the reference committee, disapproving of the Resolutions on Allotment of Residencies, was adopted on motion of Dr. Kosmak, seconded by several and carried.

It was moved by Dr. Kosmak, seconded by Dr. Thomas S. Cullen, Maryland, and carried, that section 2 (*b*) of the report of the reference committee, referring the resolution to the Council on Medical Education and Hospitals, be adopted.

On motion of Dr. Kosmak, seconded by several and carried, the report of the reference committee, with the exception of the first section that was rereferred to it, was adopted as a whole.

Report of Reference Committee on Reports of Officers

Dr. James R. Reuling, Chairman, presented a report, which as amended reads as follows:

Supplemental Session of the House of Delegates to Include Scientific Meeting: Your committee recommends that the annual supplemental session of the House of Delegates be held in various sections of the country and that this supplemental session be preceded or followed by a scientific session devoted exclusively to the general practitioner, and that the arrangements for such sessions be under the joint auspices of the Board of Trustees and the Council on Scientific Assembly.

On motion of Dr. Reuling, seconded by Dr. Charles R. Rowntree, Oklahoma, and carried after amendment to the report had been adopted, the report of the reference committee was adopted.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Elmer Hess, Chairman, presented the following report of the reference committee, which was adopted section by section and as a whole on motions of Dr. Hess, duly seconded and carried:

REPORT OF SECRETARY

1. Growth of American Medical Association: Your reference committee compliments the Secretary on his very substantial increase in membership, and with the cooperation of the state secretaries and the editors who have been influenced by his leadership.

2. Specialty Boards: Only two resolutions were referred to the Secretary, and one of these concerned changes in the requirements of specialty boards. These were referred to the proper reference committees. Your reference committee wishes to emphasize the necessity for a change in the policy of these boards.

3. Secretary's News Letter in Report of Executive Assistant: This is a step in the right direction, and the information contained in this News Letter has kept before the various medical leaders in the states and counties information of extreme value and should be continued. Comment on the information contained in the News Letter, whether critical or favorable, is welcomed. Your reference committee strongly advises the continuation of efforts for coordination of the public relations activities at headquarters and believes that the efforts made to channel back to the states and county societies is invaluable. The committee recommends that this service be enlarged and that the information be available to other organizations interested in medical affairs.

4. Promotion for Council on Medical Service in Report of Executive Assistant: Your reference committee recommends that this effort should be continued and requests that new prepayment medical service plans be given the experience of the older plans on an actuarial basis.

5. Press Section in Report of Executive Assistant: Frequently information is given to the press before that information is available to the practicing physician. Your reference committee recommends that information released to the press as new be simultaneously channeled to the profession. This will prevent the embarrassment of the physician when questioned by the laity concerning such news releases. Your committee realizes that this is difficult and it believes that a splendid contribution to public relations has been made by these news releases.

6. Appreciation: Your reference committee wishes to express its appreciation to the Board of Trustees for its foresight in obtaining as Secretary a man of the caliber of Dr. George F. Lull. It believes that under his leadership and with his experience the affairs of his office could be in no better hands.

7. Office of Executive Assistant: Your reference committee notes with deep satisfaction that this office is temporarily unfilled. It realizes the value of the office and hopes that proper personnel may soon be employed to the satisfaction of the medical profession. The Secretary and General Manager needs efficient assistance from this department.

Respectfully submitted,

ELMER HESS, Chairman.
THOMAS F. THORNTON.
ALLEN G. RICE.
ALBERT A. GARTNER.
THEODORE H. HARWOOD.

Report of Reference Committee on Miscellaneous Business

Dr. James Z. Appel, Pennsylvania, presented the following report, which was adopted section by section and as a whole on motions of Dr. Appel, duly seconded and carried after discussion:

1. Resolutions on Placing Statue of Dr. William Crawford Gorgas in New York University Hall of Fame for Great Americans: The work of Dr. Gorgas speaks for itself. Its far reaching effect on the health of humanity the world over has been particularly brought home to us during World War II. Your committee therefore believes that the provision of these resolutions should be carried out and recommends their adoption.

2. Resolution on Deductible Items for Federal Income Tax Purposes: Your reference committee recommends the adoption of this resolution.

3. Resolution on News Releases of American Medical Association: After consulting with the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, your committee has learned that THE JOURNAL is mailed each Wednesday. The Postoffice Department insists that the periodical go on sale at news stands the same date it is mailed. Thus it is impossible to control the date of news releases, particularly since the date THE JOURNAL is received by physicians varies from Friday to the Wednesday following the mailing date. Your committee therefore recommends that this resolution be not adopted.

4. Resolution on Clarification of Rules Relating to Medical Service Fees Received from the Federal Government: Your committee recognizes that with the gradual extension of government into fields of medicine with the promulgation of various rules, regulations and directives of the various bureaus, agencies and commissions, there will be great confusion and inconsistencies. It will be of great advantage to both government and medicine if this matter can be clarified as provided in the resolution. Your committee recommends the adoption of this resolution.

5. Report of the Committee on Military Rank: Since the objectives of this committee have been realized or are in process of realization, your committee recommends that the report be adopted and that the committee be discharged with the thanks of the American Medical Association.

6. Resolution on Increasing Pay of Medical Officers in the Several Services: The provisions of this resolution present no controversial problems. Its sentiments are endorsed by all. Your committee recommends adoption of the resolution.

7. Resolution on Treatment of Plastics for X-Ray Visualization: Your committee is in sympathy with the objectives of this resolution but it does not wish its action to be construed as an instruction to the legislative committee. With this in mind, your committee recommends the adoption of the resolution.

8. Report of Joint Committee for the Coordination of Medical Activities: Your reference committee believes that the work of this committee in acting as a liaison with all medical services is invaluable. It strongly urges that the committee continue to function and recommends the adoption of the report.

9. Resolution on Dissemination of Information Pertaining to Matters of Public Health: After careful study of this

resolution and the hearing of testimony from various members of the Section on Ophthalmology in which no favorable comment was obtained, your committee believes that the provisions of this resolution contain too many broad implications for this House of Delegates to accept. It therefore recommends that this resolution be not adopted.

10. Resolutions on Rebates: The fact that accepting rebates by ophthalmologists has year after year been declared unethical by the Judicial Council and such declaration has been approved by each House of Delegates to which the Council reported, it seems convincing evidence that the House of Delegates frowns on this practice. Furthermore, at this very session of the House of Delegates, you have approved a most forceful enunciation of this principle in the present report of the Judicial Council. Your reference committee can only reaffirm this principle and recommend that it be adopted.

Your reference committee, however, believes that the American Medical Association should not "request" constituent societies to expel members under any circumstances. This procedure is suggestive of and might be interpreted as dictatorship. It therefore, with the approval of the author of these resolutions, has amended them so that the last paragraph shall read: "*Resolved*, That the Secretary of the American Medical Association communicate this action to the various county societies forming the constituent associations and advise them again that members accepting rebates are violating our Principles of Medical Ethics and recommend that each component society take appropriate action whenever this situation exists."

It further amends these resolutions, without the knowledge of their author, that another "resolved" be added to it as follows: "*Resolved*, That the Board of Trustees of the American Medical Association appoint a committee to investigate all phases of this subject, including the alleged arbitrary control of the retail price of optical appliances by manufacturers, which committee is to report its findings to the House of Delegates at the next supplemental session."

In conclusion, your committee believes that the Section on Ophthalmology of the American Medical Association could and should stop this practice.

11. Resolutions on Safety in Flying: Your reference committee recognizes the dangers involved in the action of the Civil Aeronautics Administration by lowering the physical standards for private and student pilots and by permitting persons other than doctors of medicine to make these examinations. Even so soon after a great war, in which many physicians were well trained in aviation medicine, there are sections of the country in which it might be difficult to find such a trained doctor of medicine. It therefore recommends the adoption of these resolutions with a change made in the second "resolve" of the resolutions so that it shall read: "*Resolved*, That in the opinion of the Association physical examination of all grades of pilots should be conducted only by those who are doctors of medicine and preferably by such doctors of medicine who have had some training in aviation medicine." Your committee recommends the adoption of these resolutions.

12. Resolution on Care of Veterans: The request involved in this resolution cannot but be endorsed. Your committee is convinced that it is not only the desire of the medical profession but also the wish of the veteran himself that he be given home town medical care. Your committee recommends the adoption of this resolution.

13. Report of the Council on Medical Service: As has become customary, the Council on Medical Service has rendered a splendid report of the exceptionally fine work that it has accomplished the past year for organized medicine. There is very little that your committee can say in comment on this report. However, it does wish to point out the great advance that has been made in prepayment plans, which advance, it feels sure, has been due to the efforts of the Council on Medical Service. Your committee certainly must congratulate the Council on Medical Service for its News Letter. In the report the Council states "the mailing list has continued to increase in size, with the addition not only of physicians but of members of the Woman's Auxiliary, special professional societies and laymen who are interested in medical service activities." Your reference committee believes that this mailing list should continue to expand. Much of the information in the News Letter appears in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, but its conciseness and readability is much better portrayed in the News Letter. Your committee believes that very few of our Fellows read this portion of THE JOURNAL but would read these News Letters if they receive them. It therefore recommends that the House of Delegates investigate the possibility of extending this mailing list to include all Fellows of the American Medical Association, and if this is impossible that at least it be sent to all officers of component county societies. With this thought in mind, your committee recommends the adoption of the report of the Council on Medical Service.

14. Supplementary Report of the Council on Medical Service: The supplementary report of the Council on Medical Service is divided into five parts.

The first part deals with the United Mine Workers Health and Hospital Fund and particularly with the Boone Survey. Your committee agrees thoroughly and recommends that this recommendation be adopted.

The second portion of this report deals with the Veterans Administration Home Town Medical Care Program. Your reference committee believes that the recommendations of this Council will further the aims of the resolution which it has already recommended that you adopt and therefore it recommends the adoption of your Council's recommendations.

The third portion of the report deals with the American Cancer Society program, in which the Council believes that "uniform policies with reference to certain parts of this program should be developed." Your reference committee urges the Council to continue its study of the extent and experience of the programs now in operation and report its findings to the profession.

Cash Sickness Benefits: Your reference committee feels that cash sickness benefits might become a dangerous thing to medicine. It therefore recommends that your council continue its study of such legislative programs and keep the state societies informed of this study so that they will be in a position to meet any possible future legislation.

In that portion of the Council's supplementary report on the Hospital Construction Act the Council submits without comment the report of Dr. Dean F. Smiley on the definition of a health center. Your reference committee has studied this report and will only burden you with a discussion of its completeness. In his conclusions Dr. Smiley states in part: At least fourteen different functions have been assigned to health centers since 1912. Of these fourteen functions it is recommended that only five (communicable disease control efforts, sanitation, maternal-infant-child hygiene measures, vital statistics and health education) be generally included under the title of Public Health Center as that title is used in the Hospital Survey and Construction Act of 1946, and that first assistance be given to the construction of public health centers as headquarters for county and multicounty public health units rather than to more rural public health centers serving as extensions of the county and multicounty health units.

Your reference committee recommends the adoption of these recommendations as read.

Dr. Smiley further states that in rural communities from 4,000 to 18,000 in need of sick beds but not in position to afford a 50 bed general hospital, community clinics of 10 to 40 beds should be provided by hospital authorities rather than "Public Health and Medical Service Centers" provided by public health authorities.

These community clinics would offer a limited medical and maternity service but would not include major surgery or specialty services.

Your reference committee believes that there should be added to the recommendation of Dr. Smiley the statement "Such community clinics should be so organized and administered that they will not infringe on the private practice of medicine by physicians." Your committee is fearful lest even the term "hospital authorities" rather than "public health authorities" should provide a wedge by which government might enter the private practice of medicine.

Dr. Smiley further stated that, if public health centers are housed in community hospitals or community clinics, it is recommended that such centers continue to be administered independently.

With these points in mind as amended by your reference committee, it recommends the adoption of the Smiley report.

Your committee therefore recommends the adoption of the supplementary report of the Council on Medical Service.

Respectfully submitted,

James Z. Appel, Chairman.
Stephen R Monteith.
John W. Cline.
Hugh P. Smith.
Edward H. McLean.

On motion of Dr. Thomas S. Cullen, Maryland, seconded by Dr. H. B. Everett, Tennessee, and carried, the House reverted to new business.

NEW BUSINESS

It was moved by Dr. T. K. Gruber, Michigan, seconded by several and carried as amended, that the resolutions be read by title and their purpose indicated The resolutions so presented are printed in full

Resolutions on Health of the Nation

Dr. T. D. Cunningham, Colorado, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations

Whereas, The American Medical Association has often been accused *of neglect in performance of its duty regarding the medical care of* all of the citizens of the United States, and

Whereas, The federal government is currently planning drastic legislative *action concerning the health of all of the citizens of this country*; and

Whereas, The action that is planned by the government, if carried out, *would threaten the very foundations of the practice of medicine;* and

Whereas, The American Medical Association is not now equipped with all of the necessary facts either to combat the criticism leveled against us or to correct our inadequacies or the bad public condition, if such inadequacies or bad condition do exist, now therefore be it

Resolved, By the House of Delegates of the American Medical Association that each state in the United States shall be completely surveyed as to the distribution and adequacy of medical and hospital services and care, such survey to include every county in the United States and to be conducted under the direction of the organized medical profession by such skilled personnel as may be needed, and be it further

Resolved, That each state medical association be requested to report to the Secretary of the American Medical Association not later than July 15, 1947 as to whether or not that association can arrange and finance such survey in its own state, this House of Delegates directing the Board of Trustees of the American Medical Association to offer financial assistance and personnel for the conduct of such surveys in any state in which the state medical association is unable to conduct such survey without assistance, and be it further

Resolved, That such survey shall be conducted forthwith and its complete results reported to this House of Delegates at the supplemental session next ensuing

Resolution on Retired Members of House of Delegates

Dr L G Christian, on behalf of the Michigan delegation, Dr. Louis A. Buie, Section on Gastro-Enterology and Proctology, Dr Grover C. Pemberthy, Section on Surgery, General and Abdominal, and Dr Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The House of Delegates of the American Medical Association each year pays tribute in memoriam to those former members of the House of Delegates; and

Whereas, There are many former members of this House of Delegates who are now living and who have contributed greatly to American medicine and to the policies of the American Medical Association, therefore be it

Resolved, That the House of Delegates instruct the Secretary of the American Medical Association to send an appropriate letter of greetings to these men with the thanks of the House for their contributions to American medicine and to the American Medical Association

Resolution on Facilitating Efficiency of Work of House of Delegates

Dr. C. F. Strosnider, North Carolina, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, There is no central point of information concerning the times and places of the meetings of the reference committees; and

Whereas, This condition results in confusion which prevents delegates and members of the Association from appearing before committees concerning important resolutions, therefore be it

Resolved, That at future sessions of the House of Delegates of the American Medical Association a central bulletin board containing information including names of committees and hours and places of meetings be established, and that its location be announced by the Speaker of the House of Delegates

Resolution on Preparation and Presentation of Resolutions

Dr. J. D. McCarthy, Nebraska, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The efficiency of reference committees is decreased and time lost because of the lack of a standard method of preparation and presentation of resolutions; and

Whereas, This difficulty could be obviated to a great degree if there *were a model to follow; therefore be it*

Resolved, That (1) all resolutions be titled, (2) the name of the state medical society or the introducer be appended, (3) six copies be presented at the time the *resolution is read so that all members of a* reference committee may have a copy to study

Resolution on Listing Names in Daily Bulletin

. Dr K S. J. Hohlen, Nebraska, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

Whereas, The names of the registrants appearing in the *Daily Bulletin* of 1947 are arranged in alphabetical order rather than by states; and

Whereas, Such an arrangement makes it more difficult or almost impossible to locate a registrant from his state or locality, therefore be it

Resolved, That the proper authorities be requested to follow the system utilized in former years by publishing the names by states

Resolutions on Support of the SOS Collection of the Joint Distribution Committee

Dr. W. P. Anderton, New York, on behalf of a member of the Association, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

Whereas, The problems of reconstruction in Europe are the concern of all Americans and the problems of health are the particular concern of American physicians and surgeons, and

Whereas, More than 155 hospitals in D. P. camps, child care centers and other institutions are being serviced by medical teams of the joint distribution committee employing, as far as possible, European doctors, nurses and other technicians, and

Whereas, *These doctors, nurses and other technicians who survived* Nazi persecution are handicapped in their work of ministering to the needs of their shattered people by the appalling lack of equipment and *research material;* and

Whereas, Their own libraries and equipment were destroyed or looted by the Nazis; now therefore be it

Resolved, That the American Medical Association, in session assembled, voice full support of the SOS (Supplies for Overseas Survivors) Collection of the Joint Distribution Committee, major American agency aiding distressed Jews overseas, in their campaign to collect and ship medical texts and journals, equipment and supplies to European doctors; and be it further

Resolved, That this session urge the members of our profession to cooperate wholeheartedly in this campaign and contribute medical texts and journals, particularly those dealing with tuberculosis, anemia, latest methods in surgery and developments in medicine and drugs, and to send such contributions to the national warehouse of SOS at 1539 Troy Avenue, Brooklyn, N Y

Telegram from White House

Dr. F F Borzell, Vice Speaker, at the request of the Secretary, Dr. George F. Lull, who had been forced to leave the meeting, read the following night letter, receipt of which the Secretary was instructed to acknowledge with the profound thanks of the House, to which the letter had been read

Washington, D. C, June 10, 1947.

Dr. George F. Lull, Secretary and General Manager,
American Medical Association,
Hotel Traymore,
Atlantic City, N J.

Following is copy of letter addressed to Dr. Shoulders by the President under date of June 5:

Dear Doctor Shoulders:

I wish to congratulate the American Medical Association on its one hundredth anniversary and to extend to the medical profession the profound thanks of the American people for uncounted services rendered by America's doctors in war and peace.

The American genius for technical proficiency flowers nowhere more fully than in the skill of our physicians. Our capacity for organization and broad scale application of science and business methods is nowhere more apparent than in our medical schools, our laboratories, hospitals and clinics, in military and industrial medicine, and in our national, state and local public health services.

No thoughtful citizen, however, can fail to see that in achieving impersonal skills, unparalleled organization and "bigness" we have lost some of the individual and spiritual values which are the essence of our American way of life. Our family doctor has become "American medicine"; our working man, "American labor," and our storekeeper and shoemaker, "American business." In reverse, an equally deadly impersonality transforms "my patient," "my employee" and "my customer" into "the public."

Our traditions and our form of government are the world's greatest hope for individual freedom. This is because of their emphasis on the worth of the individual, his direct participation in public affairs and his freedom to become a whole man, independent in thought and action. Now, as never before, our institutions call on us to hold fast and increase the freedom of every individual for full development and use of his physical and mental powers.

We can never return to the days of the "horse and buggy" doctor; nor would we wish to. Rather, we would go forward with all the benefits of American medicine achieved and those to come. Into our methods of distributing these benefits we would infuse the personal devotion which has always been the beloved characteristic of the good physician. If every doctor will project his individual concern and care to a larger view of the needs of his colleagues and of all the people, there will be no doubt of the future growth and social value of medicine in this hazardous era which ushers in the second century of your organization.

The medical profession has been a primary leadership group in the national scene and the local community throughout this country's history. It is my hope that our physicians will give still more thought and participation as citizens to the solution of our modern problems. The problems most directly affecting their profession will claim their first attention; these include the advancement of scientific knowledge, improvement and expansion of professional training, and the extension of medical and health services. We need them also in the solution of such related problems as nutrition, housing, conditions of work, use of leisure time and other economics and environmental factors affecting health. Fortunately, physicians have, in their professional societies, channels through which to make known their individual aims and to cooperate with public and private groups.

It is to such social organizations as the American Medical Association that the nation looks for first line defense of democratic principles. In behalf, then, of the American people and for myself personally, I salute your organization and through it the men and women to whom we owe so much of personal solace in distress, to whom we entrust ourselves and those dearest to us in mankind's every vital crisis.

Very sincerely yours,

HARRY S. TRUMAN.

DR. HARRISON H. SHOULDERS, President, American Medical Association, Atlantic City, N. J.

(By WILLIAM D. HASSETT, Secretary to the President.)

On motion of Dr. William Weston, Section on Pediatrics, seconded by several and carried after discussion, the House recessed at 6 o'clock to meet at 9 o'clock Thursday morning, June 12, 1947.

(To be continued)

Washington Letter

(From a Special Correspondent)

June 26, 1947.

Medical Board to Advise Atomic Energy Commission

Seven scientists in medicine and biology have been appointed to a special medical board of review to advise the U. S. Atomic Energy Commission on atomic research in the medical and biologic fields. The group met in Washington to start work on nonmilitary phases of atomic development. Board members are Dr. Robert P. Loeb, chief, division of medicine, Presbyterian Hospital, New York, chairman; Dr. Detlev W. Bronk, chief radiologist, University Hospital, Philadelphia; Dr. Wallace O. Fenn, professor of biology, University of Rochester Medical School, Rochester, N. Y.; Dr. Herbert S. Gasser, physiologist, Rockefeller Institute for Medical Research, New York; Dr. Ernest W. Goodpasture of Vanderbilt University School of Medicine, Nashville, Tenn.; Dr. Alan Gregg, director for medical sciences, Rockefeller Foundation, New York, and Dr. A. Baird Hastings, Harvard Medical School, Cambridge, Mass.

Criticism of Health Standards in Mining Communities

Health and sanitation conditions in mining communities are criticized in a report of a four month survey of conditions in and about 260 mines in twenty-two major soft coal producing states, issued by the Coal Mines Administration of the Department of Interior and condensed in the Labor Information Bulletin for June. The article states that public health and sanitation are below standard in more than half of the mining communities, and some areas are "a disgrace to the nation." The 340 page report contains forty-seven recommendations, including establishment of a broad system of prepaid medical care for miners and their families, and improvement in the quality of medical services, public sanitation, industrial medicine, recreational activities and housing. The report says that 72 per cent of mines surveyed were inadequately prepared to provide emergency medical care to seriously injured persons. The report adds that there are occasional "tendencies to give less consideration to the quality of medical care than to profits. . . . Both management and labor appear in a few instances to have abused their responsibilities and privileges. . . . Physicians were not selected primarily on the basis of professional qualities but on the basis of personal friendships, financial tie-ups, social viewpoint or other nonmedical consideration." Conditions were reported to be generally worst in company-owned coal camps, comprising 45 per cent of surveyed mines.

House Committee Votes Funds to Start Mental Institute

The House Appropriations Committee has approved an initial appropriation of $850,000 to buy land and prepare plans for the proposed $7,500,000 Institute of Mental Health, to be built near Bethesda, Md. This was the amount asked in the President's budget. The sum covers $450,000 for land and $400,000 for plans. The institute is projected as a national mental health research center, with 200 beds for patients selected for research. It will be erected on land adjacent to the National Institute of Cancer Research on Rockville Pike.

Warm Springs "White House" Presented to Public

Basil O'Connor, president of the Georgia Warm Springs Foundation, has announced that the Little White House at Georgia Warm Springs, where President Franklin D. Roosevelt died on April 12, 1945, was to be presented on June 25 to the people of America. Governor Melvin Thompson of Georgia was to accept the deed to the property for the Franklin D. Roosevelt Warm Springs Memorial Commission created by the state of Georgia. The six room dwelling will subsequently be opened to the public.

Announcement of Allocations of Streptomycin

The Office of Materials Distribution, Department of Commerce, has announced initial streptomycin allocations for June, which total 636,800 Gm. as compared with 553,900 Gm. in May. The allocations for the armed services are 30,000 Gm.; for other government agencies, 42,000; for research, 8,450; for civilian domestic use, 456,350; for civilian export use, 100,000.

Medical Legislation

STATE LEGISLATION

Alabama

Bills Introduced.—H. 241 proposes to authorize every person of sound mind of the age of 21 years or older to designate by an instrument in writing filed in the office of the judge of probate court the **disposition to be made of his body** or parts thereof after his death. H. 256 proposes an appropriation to the state board of health to provide **streptomycin treatment of tuberculosis patients** confined in public institutions. S. 112 proposes the enactment of a law to regulate the handling, sale and distribution of barbiturates. The proposal would require **prescriptions for barbiturates** to be made only by a pharmacist on the original prescription of a person licensed to prescribe and administer barbiturates.

California

Bills Introduced.—A. 717, relating to the practice of **naturopathy,** was amended in the assembly so as to refer to naturopaths as doctors rather than naturopathic physicians. A. 1808, relating to the regulation of hospitals, was amended in the assembly by adding the proviso that no rule or regulation should be made which would prevent **the free choice by any person** who is a patient in the hospital of any physician or surgeon licensed and practicing under the Business and Professions Code. A. 2005, proposing the creation of a state **board of chiropractic examiners,** was amended in the assembly by defining an adjustment as "the act of removing an impingement by hands only" A. 2078, amending the business and professions code relating to the prescribing and **use of medicinal preparations,** was amended in the assembly by proposing that it be unlawful for any person not licensed under the provisions of division 2 of the business and professions code to use physical medicine on the body of any person, for compensation, provided that such action should not apply to the performance of physical therapy under the direction and supervision of a person licensed under the provisions of the business and professions code. S. 1278, relating to the practice of **physical therapy,** was amended in the senate so as to propose the creation of a board of physical therapy examiners and so as to define physical therapy as "the performing for compensation, received or expected, of any professional service requiring special education, knowledge or skill, by persons who undertake or represent themselves as able to treat or to alleviate ailment, deformity, fatigue, disease, injury, pain or any other physical or mental condition by physical means, including the various modalities electricity (except x-ray, radium and electrosurgery), light, heat, water, exercise and therapeutic massage." S. 1554, relating to solicitation for group hospitalization, surgical and medical care programs, was amended in the assembly by proposing that **no license should be required** in connection with the solicitation of individual or group hospitalization, surgical and medical care benefits for members or potential members of any nonprofit agricultural or horticultural organization.

Connecticut

Bill Passed.—S. 826, which passed the house June 3, proposes to repeal the **naturopathic practice act** but would provide that any person who has received a certificate of registration from the department of health entitling him to practice naturopathy in Connecticut prior to the repeal of the act would not be affected.

Florida

Bills Passed.—H. C. R. 11, which passed the house June 3, proposes the establishment of a committee to make a survey and investigation with reference to the establishment of a **medical and dental college** in the state of Florida. S. 911, which passed the house June 2, proposes to authorize the city of Jacksonville to cooperate with the state of Florida in providing a suitable site for the establishment of a **State College of Medicine and Dentistry in the city.**

Illinois

Bills Introduced.—H. 734 proposes that any person who habitually uses **narcotic drugs** or is found to be addicted thereto shall be guilty of a misdemeanor and shall be sentenced to imprisonment for a term not less than that required to effect a medical cure of the addiction and not more than one year. H. 783 proposes to authorize the department of registration and education to issue certificates of registration to naturopaths and **defines naturopathy** as "the art and science of naturopathic medicine, which includes the diagnosis, prevention and treatment of human injuries, ailments and diseases by means of any one or more of the psychological, physical or mechanical, chemical or material forces, or agencies of nature as taught by the accredited schools or colleges teaching the art and science of naturopathy." H. 791 proposes, among other things, to authorize corporations organized under the act relating to **nonprofit hospital service** corporation to act as agents for a medical service plan corporation in the solicitation of subscribers, etc. H. 792 proposes to authorize a **medical service plan corporation** to appoint a corporation existing under the nonprofit hospital service plan act to act as its agent in the solicitation of subscribers, etc. H. 872 and S. 626 propose to require the annual **registration of osteopaths** and to further require that osteopaths, at the time of their annual registration, should submit evidence that they have attended a course of refresher study of at least two days during the course of the prior year. S. 551, which passed the senate June 11, proposes to authorize the creation and establishment of a **medical center district in the city of Chicago** and to set forth the powers of the medical center commission administering such district. S. 575 proposes the establishment and operation of the Illinois Research Institute for the **Study and Treatment of Chronic Illness** and Geriatrics and makes an appropriation therefor.

New Hampshire

Bill Introduced.—S. 86 proposes to limit the sale of **barbituric acids** to the sale of prescriptions signed by a practitioner licensed by law to prescribe and administer barbiturates.

New Jersey

Bill Introduced.—A. 314 proposes an act requiring the licensing, inspecting and regulating of **private nursing homes** and private hospitals and the creation of a hospital licensing board.

Pennsylvania

Bill Introduced.—S. 846 proposes to authorize any person over the age of 16 who has been convicted of a crime to be sent to the Pennsylvania **Correctional Diagnostic and Classification Center** for diagnosis if the court is of the opinion that such person may be a defective delinquent.

Woman's Auxiliary

West Virginia

Mrs. F. Carl Chandler of Bridgeport assumed the presidency of the Woman's Auxiliary of the West Virginia State Medical Association at the twenty-third annual meeting in Charleston, May 12-14. Mrs. W. E. Hoffman of Charleston was installed as president-elect; other elective officers installed were vice presidents Mrs. John F. McCuskey, Clarksburg; Mrs. L. D. Norris, Fairmont; Mrs. T. U. Vermillion, Beckley; Mrs. Dana T. Moore, Parkersburg; recording secretary Mrs. C. J. Holley, Wheeling, and treasurer Mrs. Ross P. Daniel, Beckley. Capt. George M. Lyon (MC), U.S.N.R., of Huntington, guest speaker at the luncheon May 14, discussed the application of atomic energy in medical research. More than 225 guests attended the tea at the executive mansion Wednesday afternoon.

Illinois

The Women's Auxiliary of the Loyola School of Medicine, Chicago, held its first annual luncheon May 31. The membership numbers about 350.

Coming Medical Meetings

Alaska Territorial Medical Association, Fairbanks, July 28-30. Dr. William J. Blanton, Juneau, Secretary.

American Orthopedic Association, Hot Springs, Va., The Homestead, June 27-30. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Physiotherapy Association, Pacific Grove, Calif., July 6-12. Miss Mildred Elson, 1790 Broadway, New York 19, Secretary.

American Urological Association, Buffalo, N. Y., Hotel Statler, June 30-July 3. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Minnesota State Medical Association, Duluth, June 30-July 2. Dr. B. B. Souster, Lowry Medical Arts Bldg., St. Paul 2, Secretary.

GOVERNMENT SERVICES

ARMY

PROPOSED LEGISLATION TO IMPROVE THE STATUS OF MEDICAL OFFICERS

Hon. Robert P. Patterson, Secretary of War, noted in an address before a luncheon of the House of Delegates of the American Medical Association in Atlantic City, June 10, that it has been evident that something was irritating the medical officer of the Army ever since doctors became associated with the Army a hundred and seventy years ago. The irritation, Mr. Patterson said, did not seem to impair seriously the medical officer's work, for in war and peace he gave his services willingly and well. "It was not until the last war, when 47,000 doctors came into the Army, that we finally put our finger on the true cause of the medical officer's complaint. It was a sense of uncertainty and dissatisfaction about being able to practice his profession in a manner which would be professionally satisfying to him." The War Department is determined, Mr. Patterson continued, that the professional status of its medical officers in the future be removed from any doubt. The caliber of medical care during World War II made the army resolve to maintain the best features of that service in the years ahead.

As a step toward making army medicine a satisfying career for qualified doctors, a bill has been introduced in Congress which, in summary, provides: 1. Payment of $100 a month extra to all medical officers with less than thirty years' service. 2. Payment of an increase of 25 per cent of base and longevity pay to medical officers designated as specialists. 3. Establishment of positions for four chief consultants who would also be professors at the Army Medical Center in Medicine, surgery, neuropsychiatry and preventive medicine. These consultants would be similar in military status to professors at the U. S. Military Academy at West Point and would have an assimilated rank of brigadier or major general. They would also have authority to establish professional leadership in planning the education and careers of junior officers and in determining the professional policies that govern the care of the soldier patient. 4. Original appointments in the medical corps of outstanding specialists from civilian life, in higher grades and at later ages than are authorized at present. 5. Employment, without regard to civil service requirements, of civilian physicians in six grades at a salary of from $3,640 to $9,800. In addition, specialists would receive 25 per cent extra up to $11,000 a year. Mr. Patterson told his audience, which was composed of doctors, that "the War Department needs your support not only for this bill but for the entire program, giving the Army a medical service in peacetime equal to that of the war years."

ARMY ASSISTS IN FLOODED AREAS

The War Department announces that the Fifth Army has furnished the Red Cross, for use in the Ottumwa, Iowa, flooded area, with 54 Lister bags, a supply of calcium hypochlorite, 30,000 halazone tablets for sterilizing drinking water and many bottles of antitetanus serum. Thirty trucks with drivers were also furnished to army engineers in that area for use in hauling sand bags to strengthen the levees. In the Rutland, Vt., flood, army water supply equipment was provided to meet civilian water requirements until the city water system was again in operation. The First Army commander took steps to furnish assistance to care for thousands of displaced persons in case the Crittenden Dam, north of Rutland, failed.

At Camp Edwards, Massachusetts, and at Fort Dix, New Jersey, one company of First Army troops at each post was alerted for possible use at Rutland for flood relief duty and various detachments were sent to Vermont. Trucks were moved from Camp Kilmer, New Jersey, to Schenectady, N. Y., and made ready to move to Rutland on short notice. Medical units also were alerted.

AVIATION MEDICAL EXAMINERS

The School of Aviation Medicine, Randolph Field, Texas, graduated thirty-two officers of the Medical Corps on May 29 from the course for aviation medical examiners. The course, which covers a period of nine weeks, is designed to make medical officers proficient in the special duties required of aviation medical examiners, to familiarize them in coordinating such duties with other activities, and to indoctrinate them in flying training. Diplomas were granted at this time to the following officers:

Brig. Gen. Wallace H. Graham
Major Richard J. Brightwell.
Major Julius A. Goldbarg.
Major Philip B Watkins, M. C.
Capt. Arthur H. Coleman.
Capt. William F. Hamilton.
Capt. David H. Stoddard.
1st Lieut. Robert S. Boyd.
1st Lieut. John H. Burkhart.
1st Lieut. Earl K. Cantwell.
1st Lieut. Erin M. Dillard.
1st Lieut. Paul G. Donner.
1st Lieut. William C. Doust.
1st Lieut. James O. Fergeson.
1st Lieut. Leewan R. Kellam.
1st Lieut. Clayton H. Klakeg.
1st Lieut. Gerald J. Kochovar.
1st Lieut. Hugh B. McManus.
1st Lieut. Eustace P. Miller Jr.
1st Lieut. William E. Murphy.
1st Lieut. Niels Neustrup.
1st Lieut. George B. Nicholson.
1st Lieut. Robert M. Russell.
1st Lieut. William L. Sager.
1st Lieut. E. W. Schmidt.
1st Lieut. Carrol C. Shinn.
1st Lieut. Jesse E. Waller.
1st Lieut. George E. Wilson Jr., M. C.
Lieut. Ricardo A. Gonella, Argentine navy.
Capt. German Aguilar, Argentine army.
Major Humberto Rossetti, Argentine army.
Capt. Eduardo Subieta, Argentine army.

NEW SURGEON GENERAL TAKES OFFICE

In ceremonies at the War Department attended by officers of the General Staff and Administrative and Technical Services and members of the Surgeon General's Office, Major Gen. Raymond W. Bliss was sworn in on June 2 as the new surgeon General of the U. S. Army. Major Gen. Norman T. Kirk, whose four year term as Surgeon General had expired, in wishing General Bliss success, stated that "he will be the captain of a splendid team which has carried on in this office with an outstanding record and which has planned during the difficult interim period for the future of the department. Through the leadership of the new Surgeon General and his deputy (Brig. Gen. George E. Armstrong, who also took the oath of office at this time) and with the support of the able remaining officers of the Medical Department, I know that the future of the Medical Department is assured." General Kirk plans to retire to his new home at Montauk, Long Island.

PERSONAL

Lieut. Col. Stephen C. Sitter, M. C., has been appointed assistant chief of the neuropsychiatry consultant division in the Surgeon General's Office. He was chief of the neuropsychiatry section at Sternberg General Hospital, Manila, P. I., in 1941. Captured by the Japs at Bataan, he spent almost three years in Cabanatuan prison camp.

Capt. Peter L. Beaconsfield, M. C., was recently awarded the Croix de Chevalier de l'ordre de la Santé Publique by the French Ministry of Public Health "for outstanding contribution and devotion to the cooperative French-American medical service for all Orly Field personnel." He served with the army air transport command in the Azores, London and Paris. Captain Beaconsfield studied medicine at Oxford University in England and Georgetown University in Washington, D. C., and interned at the French Hospital in San Francisco before entering the service.

President Truman sent to the Senate in May for confirmation the names of seventeen wartime general officers for appointment to the officer reserve corps and in this list was the name of Brig. Gen. William C. Menninger of Topeka, Kan., formerly director of the neuropsychiatry division in the Surgeon General's Office.

ARMY AWARDS AND COMMENDATIONS

Brigadier General Frederick A. Blesse

The Distinguished Service Medal has been awarded to Brig. Gen. Frederick A. Blesse, M. C., U. S. Army. The citation read as follows: He performed exceptionally meritorious and distinguished service from March 1943 to April 1944. As surgeon, North African Theater of Operations, and deputy chief surgeon and chief medical inspector of Allied Forces Headquarters, General Blesse contributed notably to the high medical standards which had thus far been attained. A great improvement of the overall efficiency of the entire medical service of the Army resulted from the many new procedures, innovations and methods which he introduced and developed. The fact that the mortality rate of our forces was much lower than that of any previous campaign of any army was due, in a high degree, to his ability, judgment and leadership. General Blesse, who has also received the Oak Leaf Cluster to the Legion of Merit, graduated from Hahnemann Medical College in 1913 and entered the military service in July 1917.

Brigadier General Thomas R. Glenn

The Legion of Merit has been awarded to Brig. Gen. Thomas R. Glenn, M. C., U. S. Army. The citation read in part as follows: For exceptionally meritorious conduct in the performance of outstanding service from Oct. 1, 1940 to Feb. 20, 1942 as surgeon, West Coast Air Corps Training, Moffett Field, California, as surgeon, Air Corps Flying Training Command, subsequently Army Air Forces Training Command, Fort Worth, Texas, from Feb. 21, 1942 to Aug. 15, 1944. General Glenn through his initiative and administrative ability planned and supervised the accomplishment of an adequate medical service in pace with the accelerated expansion of the Army Air Forces. He was prominently identified with the institution and standardization of classification tests for selecting future air crew and officers. His outstanding performance of duty and distinguished service contributed to the success of the Army Air Forces Training Command and the global mission of the Army Air Forces. Dr. Glenn graduated from Jefferson Medical College, Philadelphia, in 1914 and entered the military service May 3, 1947.

Colonel John B. Flick

The Bronze Star Medal was recently awarded to Col. John B. Flick, M. C., A. U. S., of Philadelphia, for meritorious service in connection with military operations against the enemy from April 15 to Sept. 2, 1945. As surgical consultant, Office of the Surgeon, Headquarters, U. S. Army Forces, Pacific Ocean Areas, later Middle Pacific, Colonel Flick was instrumental in achieving and maintaining high standards of surgical service in hospitals throughout the command during a period of vital combat operations which culminated in the Japanese surrender. His evaluations of medical and military abilities and skills resulted in the assignment of medical officers to duties most appropriate to their training and backgrounds. The fine professional and military attainments, tact and devotion to duty of Colonel Flick were of major importance in the success of the mission of the Medical Department in the Pacific Ocean Areas.

Colonel Flick was also awarded the Legion of Merit for outstanding service as surgical consultant, Ninth Service Command, from Nov. 1, 1943 to March 30, 1945. Dr. Flick graduated from Jefferson Medical College in 1913 and entered military service Aug. 11, 1942.

Colonel Norman W. Anderson

The Legion of Merit and the Bronze Star Medal have been awarded to Col. Norman W. Anderson, M. C., U. S. Army. In the citations exceptional medical services from December 1941 to September 1944 while in the United States are mentioned. He served in turn at the Station Hospital, Camp J. T. Robinson; with the 341st Medical Regiment; as division surgeon, 30th Infantry Division, and on the staffs of the Fourth, Eighth and Ninth armies. His accomplishments in training troops, preventive medicine and operations were outstanding.

While serving with the Army of the United States he distinguished himself by meritorious service in connection with military operations on the continent from Sept. 5, 1944 to March 30, 1945. Colonel Anderson, as executive officer, Medical Section, Headquarters Ninth United States Army, was instrumental in protecting the health of the troops of the Ninth United States Army. The meritorious service of Colonel Anderson is in keeping with the high traditions of the military service. Colonel Anderson was also awarded the Purple Heart for wounds received in action in Mastricht, Holland, Dec. 31, 1944. Dr. Anderson graduated from the University of Minnesota in 1930 and was commissioned in the regular Army in July 1931.

Colonel James Barrett Brown

The Legion of Merit has been awarded to Col. James Barrett Brown, M. C., A. U. S., of St. Louis. As chief of plastic and maxillofacial surgery at Valley Forge General Hospital from June 1943 to August 1945 he performed or personally supervised the performance of 7,822 plastic surgical operations on 4,705 patients without a single death. The citation states that through consummate skill, experience and native ability he restored thousands of young men to useful lives who were otherwise faced with hopeless invalidism. By tireless energy and devotion to duty he performed a service highly distinguished in character and of lasting benefit and enduring value to society. Dr. Brown graduated from Washington University School of Medicine, St. Louis, and entered the military service June 8, 1942.

Colonel Harold W. Jones

The Legion of Merit has been awarded to Col. Harold W. Jones, M. C., U. S. Army, retired, of Washington, D. C. The citation states that under his able guidance and leadership the Army Medical Library was developed into a source of information for the entire medical profession and was raised to the high place it now occupies among the medical libraries of the world. His outstanding contributions in making the Army Medical Library one of the foremost collections of medical literature in the world will be of continuing and lasting benefit. Dr. Jones graduated from Harvard Medical School in 1901 and entered the military service in 1906.

Colonel John D. Yeagley

The Legion of Merit has been awarded to Col. John D. Yeagley, M. C., A. U. S., of Winston-Salem, N. C., who served as assistant director and later as director, Health and Sanitation Division, Institute of Inter-American Affairs, from February 1943 to November 1945. Attention is called in the citation to the fact that he demonstrated great ability in his tactful administration of an international preventive medicine program and was instrumental in improving health conditions throughout Central and South America during the war years. Dr. Yeagley graduated from the University of Pennsylvania School of Medicine in 1930 and entered the military service in June 1946.

Lieutenant Colonel Webb Haymaker

The Army Commendation Ribbon has been awarded to Lieut. Col. Webb Haymaker (then Major), M. C., A. U. S., who is cited as having served with unusual devotion and professional skill from Aug. 24, 1942 to Jan. 23, 1946, contributing materially to the professional success of the Army Institute of Pathology, especially as it concerned diseases and injuries of the nervous system. His studies and research have resulted in significant contributions to the knowledge of these conditions, and especially the brain tumors, the encephalitides, heat stroke and changes induced by poison war gases, all conditions of great importance to the military service. Dr. Haymaker graduated from the Medical College of the State of South Carolina in 1928 and entered the military service in August 1942.

Lieutenant Colonel Bradford Cannon

The Legion of Merit has been awarded to Lieut. Col. Bradford Cannon (then Major), M. C., A. U. S., of Boston. The citation states that, as assistant chief and later as chief of the maxillofacial plastic section, Valley Forge General Hospital, from March 1945 to December 1945, he performed or personally supervised thousands of plastic surgical operations. By his professional skill, sound judgment and conscientious devotion to duty he was instrumental in making it possible for young men who might otherwise have been maimed for life to return to useful and normal careers. Dr. Cannon graduated from Harvard Medical School in 1933 and entered military service April 26, 1943.

Lieutenant Colonel Thomas H. Sternberg

The Legion of Merit has been awarded to Lieut. Col. Thomas H. Sternberg, M. C., A. U. S., of Los Angeles. The citation read in part as follows: As director of the venereal disease control division, Office of the Surgeon General, he rendered exceptional services in the medical program of the Army. He directed the venereal disease treatment program at a most critical period when the schedule of treatment was being changed from the older extended treatment to the newer penicillin methods. He played an active and important role in the research on penicillin methods of treatment. Largely through his efforts the results of this research were quickly applied to the venereal disease problem in the Army, revolutionizing within an amazingly short period the entire approach to treatment of these diseases. Lieutenant Colonel Sternberg's signal achievements were a prime factor in the establishment of a record in the control of venereal diseases that reflects great credit on himself and on the Medical Corps of the Army. Dr. Sternberg graduated from Northwestern University Medical School in 1934 and entered the military service in April 1942.

Lieutenant Colonel Wayne G. Brandstadt

The Bronze Star Medal has been awarded to Lieut. Col. Wayne G. Brandstadt, M. C., U. S. Army. The citation read as follows: For meritorious service in connection with military operations, as commanding officer, 53d General Hospital (in England) from Aug. 1, 1944 to May 8, 1945. Lieutenant Colonel Brandstadt displayed superior administrative and professional ability in the treatment, care and evacuation of battle casualties. His marked leadership and exemplary devotion to duty were a constant source of inspiration to his patients and associates and contributed to the morale, efficiency and high standards attained by the Medical Department in support of operations against the enemy, thereby reflecting great credit on himself and on the armed forces of the United States. Dr. Brandstadt graduated from Rush Medical College, Chicago, in 1924 and entered the military service in 1930. He is now editor of the *Bulletin of the U. S. Army Medical Department* and secretary of the Army Medical School, Washington, D. C

Lieutenant Colonel Malcolm J. Farrell

The Legion of Merit has been awarded to Lieut. Col. Malcolm J. Farrell, M. C., A. U. S., of Waverly, Mass., who was deputy director, neuropsychiatry consultants division, Office of the Surgeon General, from April 1942 to June 1945. The citation states that he displayed exceptional ingenuity and foresight. As a result of his initiative and resourcefulness, division psychiatrists were appointed, mental hygiene consultation services were established throughout the country and a critical backlog of psychiatric patients in the Pacific Theater was eliminated. Dr. Farrell graduated from Tufts College Medical School in 1931 and entered the military service in July 1941.

Major David H. Clement

The United States of America Typhus Commission Medal has been awarded to Major David H. Clement, M. C., A. U. S., of New Haven, Conn. The citation read as follows: He rendered meritorious service as surgeon in charge of the United States of America Typhus Commission ward in the 116th Evacuation Hospital at Dachau, Germany, from May 10 to June 10, 1945. Major Clement's devoted supervision of the care of patients suffering from endemic typhus and his scrupulous attention to the management of therapy with immune serum and with para-aminobenzoic acid contributed directly to humanitarian service and to the improvement in methods of treatment of typhus fever. Dr. Clement graduated from Harvard Medical School in 1935 and entered the military service in 1941.

Major John J. Flanagan

The Legion of Merit has been awarded to Major John J. Flanagan, M. C., A. U. S., of Newark, N. J. The citation read as follows: As chief, orthopedic section, surgical service, Kennedy General Hospital, Memphis, Tenn., from January 1943 to December 1945, he devised an original operative procedure for overcoming extensive defects in the long bones by a massive sliding stepped graft. His expert professional knowledge and loyal devotion to duty insured limbs to patients threatened with permanent and total disability. Dr. Flanagan graduated from Georgetown University School of Medicine, Washington, D. C., in 1930 and entered the military service in October 1942.

Captain Henry S. Fuller

The United States of America Typhus Commission Medal has been awarded to Capt. Henry S. Fuller, M. C., A. U. S., now of London, England. The citation read in part as follows: He rendered exceptionally meritorious service in connection with the work of the United States of America Typhus Commission in the investigation of the epidemiology of scrub typhus in Assam and Burma from November 1944 to November 1945. First as member and later as director of the mite laboratory Captain Fuller reorganized and coordinated its activities in such a manner as to lead directly to the demonstration of the important mite vector of the disease and the development of a rapid survey technic for the estimation of the hazard from disease of particular areas of terrain. Dr. Fuller graduated from Harvard Medical School in 1941 and entered the military service in April 1943.

Captain Edmund A. Flexman

The Bronze Star Medal has been awarded to Capt. Edmund A. Flexman, M. C., A. U. S., of Milledgeville, Ill. The citation read as follows: He performed meritorious service from March 13 to March 22, 1944 while engaged in an extensive typhus control program in areas infested by a particularly virulent strain of scrub typhus mite on Goodenough Island in the Southwest Pacific. Realizing the risk he ran in fighting this little understood disease of high mortality rate, he nevertheless vigorously completed the epidemiologic work entailed in controlling an epidemic on the island. He made valuable recommendations to the Surgeon General for use in combating typhus fever. Captain Flexman's work is a distinct credit to himself and to the Army Medical Corps. Dr. Flexman graduated from the University of Illinois College of Medicine in 1938 and entered the military service in October 1942.

Captain Maurice C. Gephardt

Capt. Maurice C. Gephardt, now in Tokyo, has been awarded the United States of America Typhus Commission Medal for outstanding work during the typhus epidemic in Japan during the early part of 1946. The citation read in part as follows: With unfailing energy and high intelligence, Captain Gephardt dealt successfully with many novel and difficult situations. He contributed directly to the differential diagnosis of typhus fever in Japan. He assisted in training personnel and in supervising programs in typhus control in Tokyo, Osaka and Kobe as well as other locations in Japan. Captain Gephardt, acquitting himself with distinction, contributed to the advance of military and civilian preventive medicine. Dr. Gephardt graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1943 and entered the military service in September 1945.

Captain Thomas L. De Lorme Jr.

The Legion of Merit has been awarded to Capt. Thomas L. De Lorme Jr., M. C., A. U. S., now of Boston. The citation read as follows: For exceptionally meritorious service at Gardiner General Hospital, Chicago, in the development of new methods and procedures and equipment in physical therapy during the period of Feb. 26, 1944 to Aug. 1, 1945. During this period he devised apparatus and set up the program of heavy resistance exercises in the physical therapy department of this hospital, inaugurating and improving the efficiency of a new method of treatment of orthopedic cases. Dr. De Lorme graduated from New York University in 1943 and entered the military service in January 1944.

NAVY

GRADUATE MEDICAL AND TECHNICAL TRAINING

Approved residency training is being conducted in the major specialties at the naval hospitals at Bethesda, Md., Chelsea, Mass., Great Lakes, Ill., Long Beach, Calif., Oakland, Calif., Philadelphia, St. Albans, N. Y., and San Diego, Calif. A few other naval hospitals are also being used for training in obstetrics and gynecology. These hospitals were surveyed by the Council on Medical Education and Hospitals of the American Medical Association and action for full or limited approval of various training programs has since been taken by the Council in cooperation with the respective specialty boards.

In the organization of the Graduate Medical Training Program, a board of consultants to the Bureau of Medicine and Surgery was appointed, made up of members representing each of the major specialties and the Council on Medical Education and Hospitals, in order to provide closer liaison between the Council, the American specialty boards and the Navy, and to assist the Navy in establishing a program which would provide training to meet the requirements of the Council and the specialty boards. As the program progressed, consultants to the various teaching hospitals were appointed to supplement the staffs where American board members were not available in sufficient number to carry on the teaching. These consultants are giving as freely of their time as it is possible for them to do.

Residency training is being carried out in anesthesiology, dermatology and syphilology, internal medicine, neurosurgery, obstetrics-gynecology, ophthalmology, orthopedics, otolaryngology, pathology, pediatrics, psychiatry and neurology, radiology, surgery, thoracic surgery and urology. As of May 1, 1947, 152 medical officers were in residency training in naval hospitals in these specialties.

The basic sciences, as required in residency training and in the preparation for examination by the American specialty boards, are being taught in a ten months course at the Naval Medical School, Bethesda, Md. At the St. Albans naval hospital the residents are obtaining their basic sciences at New York University College of Medicine; those at Chelsea naval hospital receive them at Harvard Medical School, and those at the Long Beach naval hospital at the University of California (Southern Branch). Residents in hospitals where the basic sciences are deficient will be sent to civilian institutions or to naval hospitals where they are available later in their training period.

Ninety-two medical officers are receiving residencies, courses or fellowships in civilian institutions, such as the Lahey Clinic, Mayo Clinic, Northwestern University, Tulane University, Duke University, University of Pennsylvania, University of Michigan, Memorial Hospital (New York) and Henry Ford Hospital (Detroit).

The Medical Department of the Navy has 98 nurses in training in anesthesiology, dietetics, occupational therapy, physical therapy, psychiatric nursing and teaching and ward administration in courses at the University of Utah School of Medicine, Baylor University Hospital, University Hospitals (Cleveland), George Washington University, Medical College of Virginia, Pennsylvania Hospital (Philadelphia) and Teachers College, Columbia University (New York).

Fifty-one Hospital Corps officers are in training in sanitation, venereal disease and rodent control, law, accountancy and business administration, personnel administration, federal budgetary administration and hospital administration. Twelve hundred and ninety-one enlisted men are receiving training in aviation medicine, clerical procedures, clinical laboratory, commissary, dermatology and syphilology, diving, duplication technic, electrocardiology and basal metabolism, electroencephalography, fever therapy, malariology, medical photography, medical repair service, neuropsychiatric nursing, neuropsychiatric clerical, operating room technic, property and accounting, physical therapy, occupational therapy, spectacle dispensing, submarine training, x-ray and photofluorography, basic hospital corps instruction and intermediate course.

The audiovisual training section of the Bureau of Medicine and Surgery has in progress a series of curriculum integrated films to be used in conjunction with the Graduate Medical Training Program. While the first of these films will be in the field of basic sciences, later, it is planned to include clinical subjects.

NAVY AWARDS AND COMMENDATIONS

Vice Admiral Ross T. McIntire

The United States of America Typhus Commission Medal has been awarded to Vice Admiral Ross T. McIntire (MC), U.S.N. (retired), who as Surgeon General of the Navy rendered exceptionally meritorious service as a member of the United States of America Typhus Commission from August 1942 to June 30, 1946. The citation adds that through his expert knowledge he contributed to the formulation and operation of the commission's research and control of typhus fever in all theaters of operation. In the midst of responsibility of high governmental positions he had the problems of typhus and the utilization of the commission constantly in mind and helped to make it an effective means of controlling the spread of typhus and protecting the health of military and civilian personnel. His services increased his distinguished leadership in preventive medicine. Dr. McIntire graduated from Willamette University Medical Department, Salem, Ore., in 1912 and entered the military service May 23, 1917.

Rear Admiral Morton D. Willcutts

Read Admiral Morton D. Willcutts (MC), has been awarded the Navy Commendation Ribbon for outstanding service rendered during World War II. The citation reads in part as follows: For outstanding service as medical officer in charge of the Naval Hospital, San Diego, Calif., from June 20, 1943 to March 7, 1945. Commodore Willcutts ably directed the handling of thousands of Navy, Marine Corps and Coast Guard casualties during this period. By his professional skill and initiative in evacuating war casualties to other American hospitals and in returning physically qualified men to active duty, he maintained facilities for receiving incoming cases. His devotion to duty throughout was a contributing factor in the success of the hospital's mission and reflects the highest credit on himself and the Naval Service. Dr. Willcutts graduated from the Indiana University Medical College in 1916 and entered the naval service in 1917.

Captain George Brackett Dowling

Capt. George Brackett Dowling (MC), U.S.N., has been awarded the Honorary Officer of the Military Division of the Most Excellent Order of the British Empire. The citation makes clear that Captain Dowling was responsible for the medical arrangements for the part played by the United States Navy in the invasion of Normandy. He subsequently served in the Research Department of the Bureau of Medicine. His wholehearted cooperation with his many British colleagues was outstanding, and he was an energetic and firm supporter of United States-British liaison. He was of the greatest assistance to the British naval medical authorities both in the United Kingdom and in the United States, and his services to the Allied cause were of the greatest value. Dr. Dowling graduated from George Washington University Medical School in 1917 and entered the military service in July 1917.

Captains Brunson, Hubbard and Terry Commended

Capt. Clyde W. Brunson (MC), medical officer in command, U. S. Naval Hospital, Houston, Texas, has received a special commendation by Rear Admiral Clifford A. Swanson, Surgeon General, for the part he played in directing help to both Texas City and the hospitals in Galveston during the April 16 disaster. The commendation reads in part that, by exercise of sound judgment when the call came for help, Captain Brunson immediately dispatched ambulances, medical officers, dental officers, nurses, corpsmen and first aid equipment within twenty minutes.

Thus medical personnel and supplies arrived in Texas City in time to play a very important role in caring for the injured during the first few hours and was the first military organization at the fire. Not only did he dispatch other personnel to Texas City and to the hospital at Galveston, but his foresight in making available 500 beds for the injured, the method by which he continually dispensed supplies to that area as long as was needed, and the manner in which he continued to carry out his duties at the hospital, although short of personnel, is worthy of mention. Dr. Brunson graduated from the University of Pennsylvania Medical School in 1918 and entered the naval service in 1918.

For his outstanding performance of duty as the medical officer in command, U. S. Naval Hospital, Corpus Christi, Texas, during the Texas City disaster of April 16 Capt. H. D. Hubbard (MC), has received a special commendation by the Surgeon General of the Navy, Rear Admiral Clifford A. Swanson. The commendation reads, in part, that by the exercise of sound judgment on the part of Captain Hubbard, when the call came from the stricken city for help and when two navy planes were made available he dispatched medical officers, nurses, hospital corpsmen and supplies to the scene of the disaster, so that the medical personnel and supplies arrived at Texas City in time to play an important role in caring for the injured. Dr. Hubbard graduated from the University of Southern California Medical School in 1917 and entered the naval services in November 1917.

For outstanding performance of duty as medical officer in charge of the Naval Hospital, Houston, Texas, first aid group during the Texas City disaster April 16, 1947, Capt. Charles C. Terry (MC), has received a special commendation from the Surgeon General which reads in part as follows: The efficient and capable manner in which Captain Terry established casualty stations in the disaster area and directed the care of the injured and removal of the dead under hazardous conditions of fire and poison gases contributed in large measure toward overcoming the ill effects of this unfortunate event. He demonstrated outstanding professional ability and resourcefulness and it is considered that, as a result of his prompt and sound judgment in shifting his casualty stations and clearing the adjcent areas of all civilian and naval personnel, many lives were saved that would have otherwise been lost through the effects of subsequent explosions. Dr. Terry graduated from the University of Michigan Medical School in 1927 and entered the naval service in 1942.

Commander Robert Allan Phillips

Comdr. Robert Allan Phillips (MC), U.S.N., has been awarded the Honorary Member of the Military Division of the Most Excellent Order of the British Empire. Commander Phillips, in collaboration with Dr. Donald D. Van Slyke at the Rockefeller Institute for Medical Research, was credited in the citation for being responsible for development of an excellent and simple technic for rapid examinations of the blood in patients suffering from shock. Early information on this method was made available to British medical circles, and it proved of inestimable value in the treatment of the British wounded in Africa, Italy, Northwest Europe and Southeast Asia. Dr. Phillips graduated from Washington University School of Medicine, St. Louis, in 1929 and entered the military service in 1940.

VETERANS ADMINISTRATION

CONSOLIDATE THREE HOSPITALS

To economize in its use of doctors and nurses, the Veterans Administration has ordered consolidation of three "emergency" hospitals and transfer of 659 patients to better equipped structures. Two of the hospitals are temporary wooden wartime plants acquired as surplus from the Army and Navy. The third was leased from New York State. The shift in medical personnel will permit the Veterans Administration to open sufficient wards in its larger hospitals to offset the loss in beds. The move is expected to produce economies also in maintenance and administrative costs. The three hospitals to be consolidated are:

1. Sampson, N. Y., where 366 veterans suffering from tuberculosis are receiving treatment. These patients will be moved to the Veterans Administration hospital at Staten Island, N. Y.

2. Saratoga Springs, N. Y., where 45 general medical and surgical patients are hospitalized. These patients will be transferred to other Veterans Administration hospitals in New York state, including Brooklyn, Batavia, Bath and the Bronx. The Saratoga hospital was considered too small for economical operation.

3. Thomasville, Ga. The 248 general medical and surgical patients will be transferred to other Veterans Administration hospitals in that area. Staff shortages have prevented the Veterans Administration from operating this hospital to its full capacity.

The Sampson hospital is at the Navy's former training station on Lake Seneca. The plant will be turned back to the Navy Department for disposal. The Veterans Administration experienced difficulty in staffing its Sampson hospital with sufficient nurses.

The Thomasville hospital is the Army's former Finney General Hospital. The decision to transfer patients from this hospital results from the inability of the Veterans Administration to staff it with sufficient nurses. Employees of the three institutions will be urged to transfer to other Veterans Administration hospitals.

AUTOMOBILES FOR AMPUTEES

More than 15,000 World War II veterans who lost, or lost the use of, one or both legs had been certified as eligible under Public Law 663 to receive automobiles or other conveyances at government expense by the end of April. Of these more than 11,500 had made sales agreements with dealers for cars averaging $1,588 each, or $12 under the maximum allowable cost of $1,600. Although disabled veterans may obtain other conveyances as well as passenger cars, more than 99 per cent applied for automobiles. The appropriation for conveyances for disabled veterans authorized by Congress expired June 30.

Such disabled World War II veterans and paraplegics who obtained free automobiles from the government are receiving driving lessons from American Red Cross volunteers in cities throughout the United States; in addition, a driver-training program has been in effect in California as a cooperative project of the Red Cross, American Legion Auxiliary and the Bureau of Motor Vehicles. Although the law requires disabled veterans to hold current drivers' licenses before applying for new cars, many servicemen otherwise eligible had never driven automobiles before, and all are unfamiliar with the special handicap control appliances. The driver-training programs are designed to teach them to operate their automobile well enough to pass state driving tests and obtain state licenses.

VETERANS OF PREVIOUS WARS

During April, 105,691 veteran patients were under the care of the Veterans Administration, and of these 5 were veterans of the Civil War, 2,836 veterans of the Spanish American War, 48,340 veterans of World War I and 51,273 veterans of World War II. Patients from the regular military establishment numbered 2,808, 234 patients were retired officers and enlisted men and 195 were veterans of the Philippine Insurrection, Indian wars and lesser periods of conflict. All veterans with disabilities incurred in or aggravated by service in the armed forces are eligible for hospital care by the Veterans Administration. Veterans with non-service connected ailments may be hospitalized if beds are available and are not needed for service connected cases, and if they say they cannot pay for treatment elsewhere.

PUBLIC HEALTH OFFICERS AND THE G. I. BILL

Commissioned officers of the U. S. Public Health Service who were assigned to and served with the armed forces during World War II and are now back on duty with the Public Health Service are eligible for benefits of the G. I. bill, Veterans Administration has announced. These benefits include education or training; subsistence allowances for those in education or training, and loan guaranties for home, farm or business purposes.

The ruling was based on the case of a Public Health Service officer who served with the Coast Guard from March 1942 until January 1943, when he reverted to civilian status and returned to the Public Health Service, where he still is on duty. His military service was performed under an executive order, issued Dec. 31, 1941, in which the President directed that commissioned officers of the Public Health Service on duty with the Coast Guard shall constitute a part of the U. S. naval forces. This service was performed before the President issued the executive order, effective July 29, 1945, in which he declared the entire "commissioned corps of the Public Health Service to be a military service and a branch of the land and naval forces of the United States during the period of the present war."

The Veterans Administration has ruled that these officers are eligible to receive benefits under the G. I. bill if their release from service with the Army, Navy or Coast Guard is under other than dishonorable conditions and they otherwise meet the requirements of that act.

PERSONAL

Dr. Peter Ver Meulen has been appointed to serve as medical officer for the Veterans Administration in the upper peninsula at Escanaba, Mich. For several years Dr. Ver Meulen served the Veterans Administration at Sioux Falls, S. D.

Dr. Horace B. Cupp has been appointed manager and chief medical officer of the Lawson Veterans Administration hospital, Atlanta, Ga. Dr. Cupp formerly served at the veterans' hospital at Mountain Home, Tennessee.

Dr. Samuel A. Schuyler, New York, has been appointed chief medical officer of the Connecticut regional office of the Veterans Administration. Dr. Schuyler is a graduate of the University of London School of Medicine, a veteran of World War II and formerly was deputy medical administrator of Queen's General Hospital, Jamaica, L. I.

Dr. L. E. Bovik, Waukegan, Ill., has gone to Butler, Pa., to become chief of the surgical service at the veterans' hospital. Dr. Bovik served in both the first and second world wars.

MISCELLANEOUS

SALE OF SURPLUS GOVERNMENT PROPERTY

The War Assets Administration is conducting sales of surplus government property announced by the following regional offices. Physicians who are veterans have certain priorities in the purchase of this government property.

Regional Office, 501 W. O. W. Building, Omaha. Sale of hospital laboratory equipment and supplies including anesthesia apparatus, oxygen apparatus, hospital bed screens, bedside tables and invalid chairs.

Regional Office, Twelfth and Spruce Street, St. Louis, sale of x-ray units, stereoscopes, cystoscopes and dental chairs. Sale opened June 5 and is continuous.

Regional Office, 699 Ponce de Leon Avenue N.E., Atlanta 5, Ga. Sale of drugs, medical supplies and hospital equipment. Sale opened June 9 and is continuous.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Changes in Health Officers.—Dr. Harvey F. Hendrickson is leaving the California State Department of Health as of June 30 for health reasons. Dr. Hendrickson is a colonel in the medical corps of the regular army, retired, rather than major as stated in The Journal, May 31.

Cancer Research Unit Opens.—A cancer research unit has been established in San Francisco at the Laguna Honda Home sponsored jointly by the United States Public Health Service and the University of California Medical School. The research program will include problems of (1) electronic characteristics of normal and malignant growth, (2) physiologic changes in patients with cancer, (3) experimental clinical chemotherapy of cancer and (4) characteristics of human malignant tissues. The laboratory will be under the direction of Dr. Michael B. Shimkin, passed assistant surgeon, U. S. Public Health Service, and member of the staff of the National Cancer Institute, Bethesda, Md., and his associate Dr. Howard R. Bierman, recently Commander (U. S. N. R.) Naval Medical Research Institute, Bethesda, Md.

CONNECTICUT

Increase in Diphtheria.—Over the past nine years diphtheria in Connecticut reached a very low level. Connecticut had 36 cases in 1941, with no deaths. In 1946, however, there were 72 cases and 6 deaths in the state. The state department of health advises immunization for its control.

State Appointments.—The governor has announced the appointment of Dr. H. Bruno Arnold, New Haven, to the State Board of Examiners for Physiotherapy Technicians, and the reappointment of Dr. Joseph H. Howard, Bridgeport, to the Commission on the Care of the Chronically Ill, Aged and Infirm.

Personal.—At the meeting of the American Board of Neurological Surgery June 3 Dr. William J. German, New Haven, was elected secretary-treasurer of the board to succeed Dr. Paul C. Bucy, Chicago, whose term has expired.——Dr. Thomas P. Murdock, New Haven, chief, medical division, Meriden Hospital, was reelected chairman of the governing council of the Connecticut State Medical Society at the recent annual meeting.

ILLINOIS

Survey on Care of Chronically Ill Persons.—The Illinois Commission on the Care of Chronically Ill Persons has completed a 120 page report which recommends immediate action to construct adequate facilities for the chronically ill and to initiate research into the causes and cures of chronic illnesses. About 117,000 persons in Illinois are suffering from such ailments, the report said, and 35,000 require hospital care, although there are only 12,000 beds available for them. The research institute, proposed by Dr. Andrew C. Ivy, director of the University of Illinois schools of medicine, dentistry and pharmacy, would cost $2,500,000 to build.

Chicago

Dr. Furey Heads Chicago Medical Society.—At the annual dinner of the Chicago Medical Society June 18 Dr. Warren W. Furey took office as president of the society. Dr. J. Roscoe Miller, dean of Northwestern University Medical School, was made president-elect and chairman of the council, and Dr. Willard O. Thompson was reelected secretary. Dr. Malcolm T. MacEachern was honored as outgoing president.

Northwestern's Half Century Club Initiates Five.—Five members of the 1897 class of Northwestern University Medical School, all practicing physicians, received certificates of membership in the alumni association's Half Century Club at a luncheon June 16. They are Drs. James H. Davis, Carlinville, Ill.; S. Marx White, Minneapolis; Thomas H. Marsden, Fennimore, Wis.; Paul F. Morf, Chicago, and Albert J. Roberts, Ottawa, Ill.

Industrial Plants to Stop Polluting Water Supply.—Eighteen of the twenty industrial plants accused of dumping waste into Chicago's water supply have signed agreements to install disposal plants. The signatures were obtained as a result of suits instituted forty-four months ago by Attorney General George F. Barrett in a campaign to clean up Chicago's drinking water by prohibiting Indiana industrial plants from dumping sewage into Lake Michigan.

INDIANA

Personal.—Dr. Orva T. Kidder, Fort Wayne, has been appointed medical director of the Irene Byron Sanatorium, Fort Wayne, succeeding Dr. Merlin H. Draper, who had served as medical director since 1931 and who resigned to become medical consultant to the medical staff of Bay Pines Veterans Hospital, Tampa, Fla.

Medical Distribution Map.—The Indianapolis Medical Society has prepared a map 8 feet by 3 feet drawn to a scale of 4 inches to the mile, showing locations of various physicians by colored pins. The map hangs in the society office and has been especially valuable to young physicians who are interested in establishing their offices.

Immunization Program.—The Jackson County Medical Society in conjunction with the county public health nurse has completed an immunization program in which 1,850 children were immunized against diphtheria and 2,144 were vaccinated against smallpox. Cooperation of the medical society and community support were the keynotes in the program. Fifteen physicians participated. Groundwork for the immunization program was laid by an intensive educational campaign which included visits to schools by the public health nurse and state board of health consultant, who distributed immunization literature and showed films on immunization, and newspaper releases giving details of the program and urging parents to cooperate.

KANSAS

Personal.—Dr. Mark L. Bishoff, Topeka, chief surgeon of the Atchison, Topeka and Santa Fe Hospital Association, was honored at a recent dinner marking his retirement after forty-five years of service.

The Care of Premature Infants.—The state board of health has started the second phase of its program to reduce the number of deaths of premature infants in Kansas. In April twenty-six nurses from hospitals and public health departments attended a course on the care of premature infants. Assistance was given by staff members of the University of Kansas Medical and Nursing Schools and by representatives of the state and local health departments. In 1946 premature infant fatalities ranked as the ninth cause of death in Kansas, according to figures compiled by the state board of health.

MISSOURI

State Medical Election.—At the annual meeting of the Missouri State Medical Association in April Dr. Morris B. Simpson, Kansas City, became president. Drs. Robert Mueller, St. Louis, was made president-elect; Otto T. Blanke, Joplin, Sidney M. Bailey, Malden, and Donald M. Dowell, Chillicothe, vice presidents; Charles E. Hyndman, St. Louis, treasurer, and William A. Bloom, Fayette, secretary. The next annual meeting will be held in St. Louis.

NEW YORK

Fifteen Fifty Year Physicians Honored.—Fifteen Monroe County physicians who have practiced medicine for fifty years or more were honored at the annual meeting of the state medical society in Buffalo, May 5-9, when they received certificates at special ceremonies. These physicians are Drs. William B. Cochrane, Clifford V. C. Comfort, James C. Davis, Arthur M. Johnson, Montgomery E. Leary, Frank B. Maynard, Nathan D. McDowell, Charles Reitz, Alvah C. Remington, Joseph Roby, Jeremiah H. Sullivan, John M. Swan, Vallance A. Wickens, Charles D. Young, all of Rochester, and Horace J. Mann, Brockport.

New York City

University News.—Dr. John M. Lore, clinical professor of otorhinolaryngology, New York University College of Medicine, is the new president of the College Alumni Association.

Hospital Under Construction.—An addition to the Jewish Sanitarium and Hospital for Chronic Diseases now under construction will add 250 beds, making a total of 791. The addition will make the hospital one of the largest nonprofit voluntary hospitals for chronic diseases in the country. The six story building will include an entire floor for the management of acute illnesses and one to be devoted entirely to laboratories for routine hospital requirements as well as for research. Equipment for superficial and high voltage therapy and for hydrotherapy will be added.

Adler Memorial Meeting.—The Alfred Adler Medical Society of New York and the Individual Psychology Association, New York, held a memorial meeting May 26 observing the tenth anniversary of the death of Alfred Adler. The principal speakers were Dr. Frank L. Babbott, former president, Long Island College of Medicine, Brooklyn, who spoke on "Personal Recollections of Alfred Adler," and Heinz L. Ansbacher, Ph.D., associate professor of psychology, University of Vermont and State Agricultural College, Burlington, whose subject was "Alfred Adler's Place in Psychology Today."

Dr. Ginzburg Made Director of Surgery.—Beth Israel Hospital, 16th Street and Stuyvesant Park East, announces the appointment of Dr. Leon Ginzburg as director of surgery, effective October 1. A native New Yorker, Dr. Ginzburg graduated from the Columbia University College of Physicians and Surgeons in 1920 and continued his education abroad under an Emanuel Libman fellowship in surgery and pathology. During the war Dr. Ginzburg served as assistant chief of the surgical service of the Third General Hospital and as chief of the surgical service of the 235th General Hospital and the 25th General Hospital of the U. S. Army.

Dr. Lanza Appointed Professor of Industrial Medicine.—Officials of New York University College of Medicine, New York, recently inaugurated the Institute of Industrial and Social Medicine as a unit of its New York University-Bellevue Medical Center and announced that Dr. Anthony J. Lanza, New York, one of the nation's leading authorities in the field of industrial health, will join the institute as professor of industrial medicine. The dual announcement came at a luncheon June 3 at the Harvard Club, attended by medical directors of some of the nation's largest industries. A veteran of both world wars, Dr. Lanza holds the Legion of Merit and in 1946 received the William S. Knudsen award for the most significant contribution to the field of medicine. He is associate medical director of the Metropolitan Life Insurance Company. Dean Currier McEwen, New York University College of Medicine, said that the institute will offer training for both professional and lay workers and will award appropriate degrees. In conjunction with the institute a new general group practice clinic, staffed by members of the college faculty, will be set up. The general clinic, which will be in operation by next fall, he said, will offer to wage earners a comprehensive program of medical care. He added that there will also be offered a graduate program, not only to qualified physicians, but to others wishing to specialize in the field. The institute will also offer industry special services covering research in toxicology, physiology, worker psychology and tropical medicine. Dean McEwen announced that Dr. Lanza will voluntarily give half time service until the end of 1948, after which he will be able to devote his full time to the new program. He will act as co-director of the institute with Dr. Henry E. Meleney, professor of preventive medicine, New York University College of Medicine, New York.

OHIO

Narcotic Violation.—The Bureau of Narcotics, Washington, D. C., reports that Dr. Guy W. Fishbaugh, 3759½ Rhodes Avenue, New Boston, pleaded guilty at Cincinnati to violation of the federal narcotic law and on April 2 was placed on probation for a period of two years.

Professors to Conduct Investigation in Japan.—Dr. Katharine Dodd, associate professor of pediatrics, and Dr. Samuel Rapoport, assistant professor of pediatrics, University of Cincinnati College of Medicine, arrived in Japan the first of June on a U. S. Public Health research assignment. They will spend most of their time this summer in Tokyo investigating an acute diarrheal disease known as "ekiri."

Research in Children's Diseases.—Western Reserve University School of Medicine, Cleveland, has received a ten year grant of $250,000 from the Brush Foundation for the study of the effect of infectious diseases on infants and children. The study will be made in the department of preventive medicine headed by Dr. John H. Dingle, who will be aided by four of his associates: Drs. George F. Badger, associate professor of biostatics, and Richard G. Hodges, Charles H. Rammelkamp Jr. and Otto E. Feller, assistant professors. Delayed effects of infectious diseases will be studied in a preventive medicine clinic to be established.

Professors to Lecture in Europe.—Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati College of Medicine, will address the fourth International Congress on Microbiology in Copenhagen, Denmark, July 20-26 on "Poliomyelitis." Dr. Louis G. Herrmann, associate professor of surgery, will spend August in France, where he has been commissioned to teach in three provincial universities on "Recent Advances in Surgery." On September 8 he will address students of medicine at the University of Strasbourg. At a joint meeting in London, September 14, of the Royal College of Surgeons and the Société Internationale de Chirurgie Dr. Herrmann will give the official response to the address of Professor René Leriche, Paris, then go to the first postwar assembly of the Royal College of Surgeons of Belgium in Brussells, and thence to the fiftieth Congress of French Surgeons in Paris.

OKLAHOMA

University Appointment.—Dr. Vernon D. Cushing, for the past year resident in pathology at the University of Oklahoma Hospitals, has been appointed director of the health service of University Hospitals and Medical School and instructor in the School of Medicine. Dr. Cushing, a graduate of the University of Kansas School of Medicine, Lawrence-Kansas City, 1939, served in the army medical corps overseas in the recent war.

State Medical Election.—At the annual meeting of the Oklahoma State Medical Association May 13-16 Dr. Paul B. Champlin, Enid, was inaugurated as president. Officers elected were Dr. Clarence E. Northcutt, Ponca City surgeon, president-elect; Dr. Shade D. Neely, Muskogee urologist, vice president; Dr. Lewis J. Moorman, Oklahoma City, secretary-treasurer and editor of the state journal. Dr. Charles R. Rountree, Oklahoma City, was reelected delegate to the American Medical Association. Physicians registered numbered 675.

PENNSYLVANIA

Tuberculosis Scholarships.—Five scholarships of $300 each are being offered to young physicians, preferably those practicing in rural communities of the state, to take the graduate course at the Trudeau School of Tuberculosis at Saranac Lake, N. Y., which opens September 8 and continues for four weeks. The awards will be determined by a committee of physicians competent in the field of tuberculosis. Requests for application forms should be directed to the Pennsylvania Tuberculosis Society, 311 South Juniper Street, Philadelphia 7.

Ninth Councilor District Meeting.—At the ninth Councilor District Meeting of the Medical Society of the State of Pennsylvania at the Wanango Country Club between Oil City and Franklin, June 20, fifty year testimonials were presented to Drs. Charles A. Rogers, Freeport; Forrest J. Bovard, Tionesta; Charles R. Stevenson, Ebensburg, and John L. Hadley, Oil City (posthumously). The speakers on the scientific program included Drs. John F. Beauregar
assistant professor of Medicine,
of Medicine; Russell L. Hader
Hospital; Isador S. Ravdin, professor of surgery, University of Pennsylvania, and Moses Behrend, Philadelphia.

Philadelphia

Appoint Assistant Director of Phipps Institute.—Dr. Russell E. Teague, surgeon, U. S. Public Health Service, recently assigned to the Henry Phipps Institute of the University of Pennsylvania by the Tuberculosis Control Division of the Public Health Service, has been appointed assistant director of the institute and assistant professor of public health in the university. Dr. Teague will divide his time between his new duties at the Phipps Institute and his continuing responsibilities as consultant on tuberculosis for district 1 of the U. S. Public Health Service, which includes the New England states, New York, New Jersey, Delaware and Pennsylvania.

TEXAS

Grants Degree in Medical Art.—A degree of Master of Medical Art, the first awarded at any university, was conferred by Southwestern Medical College, Dallas, on Miss Patricia O'Neill, who has done graduate work in the medical art department during the past year. A banquet in honor of the occasion was held in the Melrose Hotel and was attended by Dallas notables in the fields of medicine and art. Many tributes were paid to Lewis Waters, Ph.G., whose self-sacrificing industry has developed the department of medical art and visual education to a unique place in medical education. Among the speakers were Dr. Edward H. Carey, emeritus professor of ophthalmology, who spoke on "Art at Southwestern."

VIRGINIA

Dr. Haag Appointed Dean.—Dr. Harvey B. Haag, professor of pharmacology, Medical College of Virginia, Richmond, on July 1 will become dean of the school of medicine to succeed Dr. Jacques P. Gray, who resigned last fall. Dr. Haag has long been associated with the college, having taken his Ph.G. degree there in 1923 and his M.D. in 1928. With the exception of a year at Cornell University Medical College, where he was assistant in pharmacology, he has been on the teaching staff of the Medical College of Virginia since 1923 and professor since 1933.

WEST VIRGINIA

Emergency Paternal and Infant Care Program Ends.—This program, in operation over the country for the past four years, will be discontinued July 1. It was created by an act of Congress for the duration of the war and six months thereafter. According to Dr. Newman H. Dyer, Charleston, state health commissioner, pregnancies occurring before June 30 will be eligible for care provided the husband is actively engaged in the armed forces in the four lower pay grades, and the child will be entitled to pediatric care for one year after birth. If the mother does not apply for this service in the first months of pregnancy, if she can prove that the pregnancy occurred prior to June 30, care for herself and her child for one year will be authorized after this date. From the inauguration of the program through Dec. 1, 1946, authorizations for care of 14,874 mothers in West Virginia were completed at a total cost of $1,159,025.02, the attendants at birth receiving $638,449.65 and the hospitals $520,575.37. For the same period care was furnished for 2,198 infants throughout the first year of life at a cost of $110,973.91, the physicians receiving $38,016.01 and the hospitals $72,957.90. During the four years the state department of health has been operating, deliveries in hospitals have increased 69 per cent and infant deaths in West Virginia have decreased from 52.4 per thousand live births in 1943 to 40.5 in 1946, the lowest ever recorded in West Virginia.

ALASKA

Appointments to the Department of Health.—The territorial department of health has increased its staff by several members. Dr. Joseph H. Marshall, a graduate of the Medical College of the State of South Carolina, Charleston, will serve as tuberculosis consultant. He has been a county health officer in Tennessee and served overseas as a major in the Army Medical Corps. A second tuberculosis consultant assigned to Juneau by the United States Public Health Service is Dr. Donald J. McMinimy, Washington, D. C. Dr. Phillip H. Moore, Greeley, Colo., is now orthopedic surgeon at Mount Edgecombe hospital. He is a graduate of the University of Oregon Medical School.

Nutritional Survey.—A three months nutrition study by the territorial department of health will be conducted this summer by Dr. Carroll F. Shukers and John R. Totter, Ph.D., associate professors of physiologic chemistry at the University of Arkansas School of Medicine, Little Rock, to appraise the nutritional status of representative sections of the population of Alaska. It will note clinical signs of malnutrition and evidence of deficiency diseases and will investigate the diets, food supply and food cost. A special effort will be made to determine the cause of corneal opacities. Biochemical determination of various nutrients in the blood and urine will be made in those areas in which eye conditions have been observed. In making this investigation Alaska Native Service personnel will work with the health department. The study has been made possible by grants from the U. S. Public Health Service, the Nutrition Foundation of New York and the U. S. Children's Bureau.

PUERTO RICO

Annual Health Report.—Puerto Rico's population continued to increase as vital statistics for the year 1945, just released, indicated a record high birth rate—42.3 per thousand inhabitants—and a new low death rate—14.1 per thousand. The population of the island in 1946 was estimated at 2,100,000 inhabitants. A decline occurred in all leading causes of death in 1945, except for diarrhea and enteritis, which showed a slight increase. A decrease of more than 20 per cent was recorded in communicable diseases. Malaria, which last year led the list of communicable diseases, dropped to third place in 1945. Highlight of the local public health program was a campaign for the immunization of children against smallpox, whooping cough and diphtheria. During 1945, the report indicates, 24,811 children were inoculated against these diseases, compared with 16,909 the previous year. The incidence of malaria is steadily decreasing. In 1945, the report adds, there were 6,168 cases reported as against 11,209 in 1944. The death rate per 100,000 inhabitants for malaria was 41.6 in 1945 against 49.9 in 1944. The morbidity rate for 1945 was 301.5 per 100,000 inhabitants, against 557.1 in 1944. House to house search and treatment of malaria was continued by 60 public health aides who made 53,445 field visits during the year and 25,202 blood smears, of which 12.1 per cent were positive. Important in the malaria control program during 1945 was the construction of permanent drainage at Santa Isabel and Ponce, the latter project operated cooperatively with the U. S. Public Health Service. At the beginning of the fiscal year 1945-46, the Federal and Insular Malaria Control Bureaus instituted a test of the value of DDT residual spraying of houses, under the direction of the U. S. Public Health Service. The municipality of Santa Isabel was chosen as the test site because of its high death and case rate and because it is typical of malarious municipalities of the south coast of the island.

GENERAL

History of Medicine Meeting.—The twentieth annual meeting of the American Association of the History of Medicine was held May 25-26 at the Cleveland Medical Library, Cleveland. "One Hundred Years Ago," a symposium, was presented by the Johns Hopkins Institute of the History of Medicine. At the dinner session Dr. John F. Fulton, New Haven, Conn., gave an address on Harvey Cushing.

Aero Medical Awards to Drs. Bauer and McFarland.—The Aero Medical Association has just established two annual can Medical Association during the convention in Atlantic City June 4-6. The Theodore C. Lyster Award for contributions to aviation medicine in general was given to Dr. Louis H. Bauer, Hempstead, N. Y., editor of the *Journal of Aviation Medicine* and one of the founders of the association.. The Raymond F. Longacre Award for contributions to aviation medicine in the fields of neuropsychiatry or psychology went to Ross A. McFarland, Ph.D., Cambridge, Mass.

Articles Lost at Atlantic City.—The office of the American Medical Association during the convention in Atlantic City received a number of personal objects which were found in the hall, all of which except a very few have been returned to their owners: There remain a pair of polaroid sun glasses made by V. R. Tedesco, 17 Hanson Place, Brooklyn 17, New York, and some keys including apparently house and car keys; also a pair of eye glasses, some gloves and other personal objects. If the owners care to communicate with the Headquarters Office of the American Medical Association in Chicago, addressing Mr. A. R. Stack, these will be returned.

American Heart Association Election.—At the annual meeting of the American Heart Association in Atlantic City June 6-7 Dr. Arlie R. Barnes, Rochester, Minn., assumed the presidency and Dr. Tinsley R. Harrison, Dallas, Texas, was made president-elect. Other officers elected included Drs. Carl J. Wiggers, Cleveland, vice president; Harry E. Ungerleider, New York, secretary, and Mr. Samuel Harrell, Indianapolis business man, treasurer. In accordance with the plan of reorganization, which calls for the election of laymen as well as physicians to the governing bodies of the association, Thomas I. Parkinson, president of the Equitable Life Assurance Society of the United States, was named chairman of the board of directors. Continuing in their present posts will be Drs. Harold M. Marvin, New Haven, Conn., executive secretary; David D. Rutstein, New York, medical director, and Charles A. R. Connor, New York, associate medical director.

Three New Research Grants.—The award of three new research grants and renewal of a fourth have been announced by Sharp and Dohme, Inc., Philadelphia. A grant to Dr. Oswald P. J. Falk, consultant at the St. Louis City Hospital, St. Louis, will support a clinical study to evaluate caronamide as an adjunct to penicillin in the treatment of infectious diseases. Dr. Charles N. Hendricks, El Paso Medical and Surgical Clinic, El Paso, Texas, received a grant in support of a clinical study and use of tyrothricin and other preparations as an aerosol. The third research grant went to Dr. Marshall C. Cheney, physician in charge of student health, University of California, Berkeley, Calif., in support of his research into the prevention of the common cold by means of respiratory vaccines. The company also renewed a grant to Tulane University of Louisiana, New Orleans, in support of C. Gordon Johnson's research program in connection with problems involving phthalylsulfathiazole and sulfamerazine in preoperative and postoperative urinary tract infections.

Education of School Children on Role of Animal Experimentation.—Through the active cooperation of the National Teachers Association, the National Society for Medical Research will initiate a plan for education in elementary and secondary schools on the role of animal experimentation in medical research. The National Science Teachers Association, a department of the National Education Association, has as its objective the improvement of science teaching at all educational levels. The association regularly sends out informational packets to 5,000 science teachers in various parts of the country and to the membership of 30 science teachers associations affiliated with the National Science Teachers Association. First step in the society's plan for work with science teachers will be the establishment of a joint committee to develop materials useful in teaching. Mr. Tom J. Blakley, assistant secretary of the National Society for Medical Research, is at present working on final drafts of educational leaflets and announces that the joint committee will be set up in the immediate future.

Conference on Conservation, Nutrition and Human Health.—This conference will be held June 28-29 at Ohio University, Athens, Ohio, by Friends of the Land in cooperation with the University. Discussions will present the relationships that exist between the quality of the soil and the health of the people who live on it. Among the speakers Saturday will be Dr. Axel Emanuel Hedback, Minneapolis, who will discuss "The Aging of Man"; Dr. Paul R. Cannon, Chicago, "Building Stones of Health"; Milburn L. Wilson, Ph.D., "Giving the People of the United States an Optimal Food Supply," and J. Russell Smith, Ph.D, "Plan or Perish." On Sunday Curt P. Richter, Ph.D., will speak on "Instinctive Dietary Habits"; Ladd Haystead, "The Future of Farm Life in America"; Warren S. Thompson, Ph. D., "Population Problems of the United States"; Robert Cook, editor of the *Journal of Heredity*, "Conservation of Soil and Genes"; C. M. Long, "Taking the Farm to the Clinic—Diagnosis and Treatment," and Dr. Jonathan Forman, Columbus, "Current Thinking on Nutrition."

American Urological Association.—This association will hold its annual meeting June 30-July 3 at the Hotel Statler, Buffalo. In addition to numerous members of the association and invited guests, the following will address the scientific sessions: Dr. Terence Millin, London, England, on "Retropubic Prostatectomy"; Dr. Armando Trabucco, Buenos Aires, "Congenital Sterility"; Ju Chen Hsiung, Shanghai, China, "Influence of Mineral Oil on the Absorption of Diethylstilbestrol from the Gastrointestinal Tract." Dr. Jack Lapides, Ann Arbor, Mich., will deliver the winning prize essay of the Committee on Research on "The Physiology of the Intact Human Ureter." The association will present its second annual award for research on the human male reproductive tract to Dr. Robert S. Hotchkiss, New York, who will address the session on "Reflections on Infertility in Men." The presidential address by Dr. Charles McMartin, Omaha, will be delivered July 3 on "Teaching Urology to the Undergraduate." It will be followed by the Ramon Guiteras Lecture by Dr. George W. Thorn, Hersey professor of the theory and practice of physic, Harvard Medical School, on "Treatment of Renal Insufficiency."

Dr. Clarence E. Moore of Pennsylvania Wins Golf Championship.—At the annual American Medical Golfing Association tournament, Atlantic City, June 9, Dr. Clarence E. Moore, Harrisburg, Pa., won the Will Walter Trophy and the championship of the American Medical Golfing Association with a score of 148 for 36 holes over the Linwood Country Club course. The handicap championship for 36 holes and the Detroit Trophy went to Dr. George N. Hemmer, Syracuse, N. Y. In the 18 hole contest Dr. Regis A. Wolff, Pittsburgh, won the Golden State Trophy for the best gross score, and Dr. Eugene E. O'Neal, Boston, bagged the Ben Thomas Trophy with the best net; Dr. William H. Glass, East Orange, N. J., took home the Atlantic City Trophy as the runner-up. The day's second best gross score for 36 holes was made by Dr. Delon A. Williams, Kansas City, who has his name engraved on the St. Louis Trophy, emblematic of championship in flight A. Dr. Thomas A. Kyner, Kansas City, won the President's Trophy, presented by Dr. James W. Morgan of San Francisco, for the handicap championship in flight A. In the event limited to Fellows 60 years of age or older, the Minneapolis Trophy went to Dr. William C. Speidel of Seattle. Dr. Erastus S. Edgerton, Wichita, Kan., won the Wendell Phillips Trophy in the "Old Guard" event, limited to past presidents of the A. M. G. A.

Section Event

Seven sterling silver bowls were presented by the San Francisco Medical Society to the following winners in the section event:

General Practice	Dr. Albert M. Donato, Indianapolis.
Internal Medicine	Dr. Peter F. Harrington, Providence, R. I.
Surgery	Dr. C. G. Prather, Westwood, N. J.
Obstetrics and Gynecology	Dr. David H. Houston, Seattle.
Eye, Ear, Nose and Throat	Dr. Sylvester E. Lentz, Lehighton, Pa.
Proctology	Dr. James W. Morgan, San Francisco.
Other Specialties	Dr. Sheldon H. Stuurmans, St. Paul.

Special prizes were presented to Dr. José Valls, Buenos Aires, president of the Argentina Medical Association, who came the greatest distance to the tournament, and to Dr. Baxter H. Timberlake, Atlantic City, for a hole in one.

Election

Dr. Waltman Walters of Rochester, Minn., was chosen president of the American Medical Golfing Association for the ensuing year. Dr. William C. Speidel, Seattle, was elected first vice president and Dr. Jean A. Gruhler of Atlantic City second vice president. Bill Burns and J. Lyn Leet of Lansing, Mich., were reelected secretary-treasurer and assistant secretary-treasurer respectively. The next annual tournament will be held in Chicago in June 1948.

Deaths in Foreign Countries

Sir Frederick G. Hopkins, noted for his work on the growth promoting vitamins and a joint winner of the Nobel Prize for medicine in 1929, president of the Royal Society 1930-1935, died May 16, aged 86.

CORRECTION

Radio Broadcasts at Atlantic City.—In the leading editorial in The Journal June 21 it was stated (p. 696) that the Mutual Broadcasting System "duplicated" a broadcast in the series "Stephen Graham—Family Doctor" at the Monday night dinner of the House of Delegates. This was not a duplicate performance but the origination of the actual nationwide broadcast in the presence of the guests at the dinner. Reference should have been made to the cooperation of the Columbia Broadcasting System in the broadcast of "The Two Worlds of Dr. Frederick Banks" on June 7 in commemoration of the Centennial and in broadcasting the speech of the President of the Association, Dr. Edward L. Bortz; also of the cooperation of the Mutual network in broadcasting an interview with Dr. Bortz.

Marriages

Hugh Edward Tyner, Leaksville, N. C., to Miss Anna Katherine Bell of Morehead City in Winston-Salem March 8.

William Clark Thomas Jr., Gainesville, Fla., to Miss Brenda A. Wiltshire of Buenos Aires, Argentina, recently.

Stonewall Jackson Van Hook, Whitehaven, Tenn., to Miss Gladys Mae Scarbrough of Maryville March 1.

William Harper Weiss, Fairmont, W. Va., to Miss Rosemarie Lauer of Decatur, Ill., in St. Louis March 4.

Jerome Victor Treusch to Miss Constance Gloria Ripley, both of Beverly Hills, Calif., Dec. 8, 1946.

Harry S. Douglas, Washington, D. C., to Miss Bernadine Curley, of Billings, Mont., Dec. 14, 1946.

Edward S. Crosland, Reno, Nev., to Miss Esther Buckwalter of Leola, Pa., in San Francisco recently.

Harrie Rogers Chamberlin, Belmont, Mass., to Miss Betsy Inches of Chestnut Hill, Dec. 17, 1946.

Millard B. White, Tampa, Fla., to Miss Mary Elizabeth Snow of Savannah, Ga., Dec. 26, 1946.

Lester James Talbot, Bala-Cynwyd, Pa., to Miss Dorothy Harrison of St. Davids February 15.

Alfred N. Smith, Calmar, Iowa, to Miss Mary Louise Wyman of Yampa, Colo., recently.

Adron A. Sullenger, Marion, Ind., to Miss Cuma Cottingham of Indianapolis March 8.

Louis Spigelman, Jamaica, N. Y., to Miss Doris Altman of Corona recently.

Deaths

Ulysses Silver Kann ⊕ New York; Université de Paris Faculté de Médecine, France, 1901; an Affiliate Fellow of the American Medical Association; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; fellow of the New York Academy of Medicine and American College of Physicians; past president of the Broome County Medical Society and the Binghamton Academy of Medicine; served with the National Guard on the Mexican border in 1916 and in France during World War I; for many years on the staffs of the Ideal Hospital in Endicott, Tioga County General Hospital in Waverly, Broome County Tuberculosis Hospital in Chenango Bridge, Binghamton City Hospital and the Binghamton State Hospital; died in the Lenox Hill Hospital April 7, aged 74, of coronary thrombosis.

Thomas Hendrick Russell ⊕ New York; Jefferson Medical College of Philadelphia, 1908; member of the founders group of the American Board of Surgery; assistant director and professor of clinical surgery at the New York Post-Graduate Medical School; fellow of the American College of Surgeons; member of the New York Surgical Society; consulting surgeon at the Gouverneur Hospital in New York, St. Joseph's Hospital in Far Rockaway, Nyack (N. Y.) Hospital, Rockaway Beach Hospital in Rockaway Beach, St. Agnes Hospital in White Plains and the Jersey City Medical Center in Jersey City; director of the surgical service at New York Post-Graduate Hospital and Dispensary; died April 5, aged 61, of coronary thrombosis.

James Richey Horner, Cleveland; Homeopathic Hospital College, Cleveland, 1883; New York Homeopathic Medical College, New York, 1884; Western Reserve University Medical Department, Cleveland, 1907; formerly professor of nervous and mental diseases at the Cleveland Homeopathic Medical College; served on the staff of the Cleveland City Hospital, as president of the staff of the Cleveland Homeopathic Hospital and as secretary of the American Institute of Homeopathy; until 1942 secretary of the staff of the Huron Road Hospital in East Cleveland, where he died March 20, aged 86, of carcinoma of the sigmoid and uremia.

Richard Burgess Webb ⊕ Paintsville, Ky.; University of Louisville School of Medicine, 1932; interned at the Hillman Hospital in Birmingham, Ala., Highsmith Hospital in Fayetteville, N. C., and the Aultman Hospital in Canton, Ohio; served a residency at the Colorado Springs (Colo.) Psychopathic Hospital; began active duty as a lieutenant in the medical corps, Army of the United States, in May 1942; served nine months overseas in the Asiatic and the Pacific theaters; separated from the service with the rank of captain on April 22, 1946; died June 30, 1946, aged 40, of coronary thrombosis.

Joseph Stokes ⊕ Moorestown, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1883; past president of the Burlington County Medical Society; since 1933 chairman of the board of trustees and past president of the Burlington County Trust Company; served as president of the Moorestown National Bank; for many years affiliated with the Friends School; served on the board of the Friends Hospital in Philadelphia; on the visiting staff of the Burlington County Hospital in Mount Holly; died April 7, aged 85, of hemiplegia and hypertensive cardiovascular disease.

Lisbon C. Allen, Hoschton, Ga.; University of Georgia Medical Department, Augusta, 1888; member of the American Medical Association; formerly member of the state legislature; for many years member of the board of trustees of the local schools; served as bank president; died in the Piedmont Hospital, Atlanta, March 6, aged 84, of adenocarcinoma of the colon.

James Archie Barker, Ames, Iowa; State University of Iowa College of Medicine, Iowa City, 1900; served during World War I; at one time governor of Battle Mountain Sanatorium in Hot Springs, S. D.; served on the staffs of the Veterans Administration facilities in Lincoln, Neb., in Bath, N. Y. and others; died in Biloxi, Miss., March 9, aged 71, of carcinoma of the stomach.

George Crawford Beekman, Middletown, N. J.; New York University College of Medicine, New York, 1940; interned at the Lenox Hill Hospital in New York, where he served a residency; diplomate of the National Board of Medical Examiners; served during World War II; died in the Riverview Hospital in Red Bank, March 23, aged 32, of a fracture of the skull and crushed chest received when a tractor he had been driving toppled down an embankment.

David Eliot Bixby ⊕ Cleveland; Eclectic Medical College, Cincinnati, 1921; member of the American Psychiatric Association; for many years affiliated with the Cleveland State Hospital; died in the Cleveland Clinic Foundation Hospital April 4, aged 63, of complications following a gallbladder operation.

John McCue Bowcock, Williamson, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1901; on the staff of the Williamson Memorial Hospital; died March 20, aged 72, of coronary thrombosis.

Irene Ballou Bullard, Charlottesville, Va.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; died March 21, aged 70, of cerebral hemorrhage.

Marshall Dickson Carnell, Okmulgee, Okla.; University of Nashville (Tenn.) Medical Department, 1908; member of the American Medical Association; formerly superintendent of health of Okmulgee County and health officer of Sequoyah County; died in the Mayo Clinic, Rochester, Minn., February 22, aged 69, of heart disease.

Harry Everette Carver, Earlham, Iowa; State University of Iowa College of Homeopathic Medicine, 1899; member of the American Medical Association; past presiednt of the Madison County Medical Society; served during World War I; died in the Veterans Hospital in Des Moines, March 18, aged 72, of coronary thrombosis.

Timothy Joseph Casey ⊕ Oakland, Calif.; John A. Creighton Medical College, Omaha, 1916; served during World War I; consultant to the Veterans Administration; died February 10, aged 57, of heart disease.

Claud North Chrisman, Dayton, Ohio; Miami Medical College, Cincinnati, 1895; member of the American Medical Association; past president of the Montgomery County Medical Society; for many years on the staff of St. Elizabeth Hospital, where he died March 23, aged 77, of acute myocarditis and influenza.

Roy Cross, Kansas City, Mo.; University Medical College of Kansas City, Mo., 1908; at one time teacher of chemistry at his alma mater; died in St. Luke's Hospital March 22, aged 63, of cerebral hemorrhage.

Alfred Green Doust, Syracuse, N. Y.; Syracuse University College of Medicine, 1887; served on the staff of the Crouse-Irving Hospital; died in the Syracuse Memorial Hospital March 15, aged 82, of arteriosclerosis and pneumonia.

Robert Lamar Drury, St. Louis; Washington University School of Medicine, St. Louis, 1934; member of the American Medical Association; served during World War II; served on the staffs of the Missouri Baptist Hospital, St. Luke's Hospital and the Frisco Employes' Hospital, where he died March 20, aged 37, of endothelioma with metastasis.

Lester Julian Efird ⊕ Tampa, Fla.; University of Maryland School of Medicine, Baltimore, 1903; served overseas during World War I; died in Winston-Salem, N. C., March 21, aged 68, of hypertensive cardiovascular disease.

John Ebenezer Evans ⊕ Wilmington, N. C.; University of Maryland School of Medicine, Baltimore, 1916; served during World War I; on the staff of the James Walker Memorial Hospital; died March 22, aged 56, of coronary thrombosis.

Rose Cecilia Faughnan ⊕ Passaic, N. J.; Woman's Medical College of Baltimore, 1910; formerly affiliated with the U. S. Public Health Service; served as physician for the board of education of Newark, where she had been on the staff of St. James Hospital; died March 26, aged 73, of bronchopneumonia and adenocarcinoma of the bladder.

Walter Wallace Fenton, San Bernardino, Calif.; Vanderbilt University School of Medicine, Nashville, 1914; school physician; formerly affiliated with the U. S. Public Health Service reserve; county health officer for many years; served during World War I; died in Loma Linda Sanitarium and Hospital in Loma Linda March 21, aged 68, of coronary heart disease.

John Harvey Fouts, Franklin, N. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1895; died March 8, aged 82, of coronary thrombosis.

Patterson Tilford Frazer Jr., Hopkinsville, Ky.; Meharry Medical College, Nashville, Tenn., 1913; served during World War I; died March 30, aged 57, of influenza and pneumonia.

Edward Frothingham ⊕ Woodhaven, New York; New York Homeopathic Medical College and Hospital, New York, 1918; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; on the staff of the Brooklyn Eye and Ear Hospital; died in the Methodist Hospital in Brooklyn, March 22, aged 54, of cerebral hemorrhage.

Arthur Louis Gagnon, San Diego, Calif.; Rush Medical College, Chicago, 1900; member of the American Medical Association; served on the staffs of the Norwalk (Calif.) State Hospital and as attending physician at the Nazareth Orphanage in Mission Valley; formerly on the staff of the Mercy Hospital; at one time medical examiner for the county welfare department; died March 26, aged 73, of coronary thrombosis.

Julius Golembe, New York; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1924; member of the American Medical Association; served during World War I; on the staff of the Mount Sinai Hospital; died March 19, aged 50, of coronary thrombosis.

John Hurter Gordon ⊕ Birmingham, Mich.; Tufts College Medical School, Boston, 1919; fellow of the American College of Surgeons; served as chief of staff of St. Joseph Mercy Hospital in Pontiac; served during World War I; died on a train between Palm Beach and Winterhaven, Fla., March 2, aged 56, of coronary thrombosis.

Charles Orson Gose ⊕ Hennessey, Okla.; Keokuk (Iowa) Medical College, 1894; served as director of the Farmers and Merchants National Bank; died in the Oklahoma City General Hospital, Oklahoma City, March 8, aged 79, of cancer.

Joseph John Gramling ⊕ Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; died March 18, aged 68, of coronary occlusion.

Willis Curtis Groce, Byrdstown, Tenn.; University of Nashville Medical Department, 1905; died March 31, aged 68, of heart disease.

James Morgan Grove, Cherokee, Iowa; Harvey Medical College, Chicago, 1903; member of the American Medical Association; on the staff of the Cherokee State Hospital, where he died March 28, aged 76, of arteriosclerotic heart disease.

Solomon Augustus Hatfield ⊕ Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1912; clinical professor of medicine at his alma mater; member of the city board of health and the Columbus Academy of Medicine; formerly superintendent of the Starling-Loring Hospital; on the staffs of the University, St. Francis, Grant and St. Anthony's hospitals; died March 23, aged 58, of coronary occlusion.

Jacob Davis Hershey ⊕ Manheim, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; past president of the Lancaster County Medical Society; formerly burgess of Manheim; served as deputy coroner; county coroner from 1927 to 1935; died in the Lancaster (Pa.) General Hospital March 5, aged 71, of uremia.

Harold Crawford Hill ⊕ Holyoke, Colo.; Rush Medical College, Chicago, 1914; fellow of the American College of Surgeons; superintendent and medical director of the Holyoke Hospital, where he died March 12, aged 57, of coronary occlusion.

Lyndon M. Hill, Atlanta, Ga.; Meharry Medical College, Nashville, Tenn., 1911; served as president of the National Medical Association; died in the Harlem Hospital in New York March 17, aged 66, of carcinoma of the vertebrae.

Wilson Warren Holmes, Keokuk, Iowa; Keokuk Medical College, 1892; member of the American Medical Association; on the staffs of the St. Joseph Hospital and the Graham Hospital, where he died March 20, aged 78, of cerebral hemorrhage.

William Amos Holt, San Diego, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; died in National City March 29, aged 85, of mesenteric thrombosis, arteriosclerosis and cerebral hemorrhage.

Frank Albert Hubbard, Columbus Junction, Iowa; Keokuk Medical College, 1895; member of the American Medical Association; served in France during World War I; died March 21, aged 79, of cerebral hemorrhage.

Thomas Franklin Hudson ⊕ Luxora, Ark.; Memphis (Tenn.) Hospital Medical College, 1907; secretary of the Mississippi County Medical Society; killed March 20, aged 64, when the automobile in which he was driving was struck by a train.

King Lyman Hull, Bloomfield, Ind.; Indiana University School of Medicine, Indianapolis, 1929; member of the American Medical Association; past president of the Greene County Medical Society; county coroner; on the staff of the Freeman Greene County Hospital in Linton, where he died March 16, aged 49, of coronary thrombosis.

Henry L. Kirkpatrick, White Sulphur Springs, W. Va.; Medical College of Ohio, Cincinnati, 1881; member of the American Medical Association; served as a member of the Fayette County Court; died March 15, aged 92, of congestive heart failure.

Edwin Jay Koontz, Wadsworth, Ohio; Cleveland University of Medicine and Surgery, 1896; member of the American Medical Association; on the staff of the Wadsworth Municipal Hospital; died March 1, aged 76, of cardiovascular renal disease.

Lyman Converse Lewis ⊕ Belmont, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; served as president and secretary of Allegany County Medical Society; since 1915 health officer of the consolidated health district of Amity-Belmont; served during World War I; on the staff of the Jones Memorial Hospital in Wellsville, where he died March 21, aged 70, of coronary thrombosis.

William Lomax, Evansville, Ind.; Medical College of Indiana, Indianapolis, 1881; died in Indianapolis March 12, aged 92, of coronary occlusion and chronic nephritis.

Frank E. McCurtain, Denver; Denver College of Physicians and Surgeons, 1897; died in March, aged 76, of lung abscess and lobar pneumonia.

John Bertral McKenzie, Wilmington, Ohio; Starling Medical College, Columbus, 1900; died in Lake Worth, Fla., March 8, aged 73, of coronary thrombosis.

Cleveland Charles MacLane ⊕ Chicago; Loyola University School of Medicine, Chicago, 1917; on the staffs of the Illinois Masonic and St. Bernard's hospitals; served during World War I; died in Tucson, Ariz., March 16, aged 63, of emphysema.

George Elzear Maley, Galesburg, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; died March 20, aged 66, of heart disease.

William J. Maurits, Morrison, Ill.; Detroit College of Medicine, 1900; member of the American Medical Association; died in St. Luke's Hospital, Chicago, March 24, aged 71, of bronchogenic carcinoma.

Frank Richard Morrow ⊕ Miami, Fla.; Ohio State University College of Medicine, Columbus, 1927; specialist certified by the American Board of Internal Medicine; for many years on the staff of the Jackson Memorial Hospital; died March 5, aged 45, of pulmonary edema.

Harry G. Nicks ⊕ St. Louis; Ensworth Medical College, St. Joseph, Mo., 1890; formerly professor of physical diagnosis and practice of medicine at the St. Louis College of Physicians and Surgeons; died March 24, aged 85, of monocytic leukemia.

William T. O'Halloran ⊕ Boston; Tufts College Medical School, Boston, 1924; assistant professor of medicine at the Boston University School of Medicine; fellow of the American College of Physicians; physician in chief of the sixth medical service at the Boston City Hospital; died March 21, aged 48, of hypertensive heart disease.

John Henry Outland ⊕ Kansas City, Mo.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; died in Laguna Beach, Calif., March 24, aged 76, of cerebral thrombosis.

William Thomas Owens, Hartford, Conn.; University of Vermont College of Medicine, Burlington, 1899; served as officer in the state national guard, on the Mexican Border and during World War I; on the staffs of the Hartford and St. Francis hospitals; died March 13, aged 71, of pulmonary tuberculosis.

Herman B. Parker, Guayaquil, Ecuador; University of Pennsylvania Department of Medicine, Philadelphia, 1896; formerly affiliated with the U. S. Public Health Service; died in Miami, Fla., March 16, aged 72, of embolus of the right colic artery.

Charles Orley Peters, Erie, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; member of the American Medical Association; served during World War I; on the staff of St. Vincent's Hospital; died February 1, aged 60, of bronchopneumonia and Parkinson's disease.

Albert Pfeiffer, Fremont, Ohio; Louisville (Ky.) Medical College, 1893; formerly coroner of Allen County; served during World War I; served on the staff of the Lima State Hospital; died March 21, aged 89, of arteriosclerotic gangrene.

Charles Jacob Pflug, Brooklyn; University of the City of New York Medical Department, New York, 1895; member of the American Medical Association; fellow of the American College of Surgeons; surgeon, South Side Hospital in Bay Shore; consulting surgeon, St. Catherine's and Wade hospitals; attending surgeon, Wyckoff Heights Hospital, where he died March 22, aged 73, of acute coronary occlusion, diabetes mellitus, arteriosclerosis and gangrene of left big toe.

Barnie Lee Piper, Georgiana, Ala.; Emory University School of Medicine, Atlanta, 1916; member of the American Medical Association; died in Roanoke March 17, aged 59, of nephritis.

Lafayette Oren Roberts, Portland, Ore.; University of Oregon Medical School, Portland, 1912; member of the American Medical Association; served during World War I; died March 19, aged 66, of coronary sclerosis.

Charles Bradford Rodes ⊕ Butte, Mont.; St. Louis University School of Medicine, 1908; specialist certified by the American Board of Radiology; member of the American College of Radiology; served as medical director of the Murray Hospital; died March 31, aged 67.

Morris Martin Rottman ⊕ Chicago; Chicago Medical School, 1929; served during World wars I and II; on the staffs of the Grant and Cuneo hospitals; died March 15, aged 47, of coronary thrombosis.

Rubin Ryvkin, Berlin, N. Y ; Universita Karlova Fakulta Lékařská, Prague, Czechoslovakia, 1928; died February 5, aged 48, of coronary occlusion.

Henry T. Schildroth, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C, 1893; formerly coroner of St. Clair County, Ill.; on the staffs of the Georgetown University Hospital and the Providence Hospital, where he died March 29, aged 80, of arteriosclerosis.

Walter Shropshire, Yoakum, Texas; Missouri Medical College, St. Louis, 1890; past president of the Lavaca County Medical Society; formerly vice president of the State Medical Association of Texas and councilor of the Eighth District; served as city health officer; died April 3, aged 84, of hypostatic pneumonia and myocarditis.

George Sinnamon, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1889; member of the American Medical Association; for many years police surgeon; on the staffs of the Stetson Hospital and the Episcopal Hospital, where he died March 10, aged 78, of cerebral hemorrhage.

Irving William Slack, Tampa, Fla.; University of Vermont College of Medicine, Burlington, 1911; died February 28, aged 80, of coronary thrombosis

Guy Beckley Stearns, New York; New York Homeopathic Medical College and Hospital, New York, 1900; formerly professor of materia medica at his alma mater; died March 25, aged 76, of carcinoma.

John Anthony Steinwandel, Philadelphia; Jefferson Medical College of Philadelphia, 1890; on the staff of the Jefferson Hospital; died March 30, aged 86, of heart disease.

Ralph Methven Thomson, Savannah, Ga.; Medical Department of Tulane University of Louisiana, New Orleans, 1898; died March 24, aged 71, of pneumonia

Lieut. William S. Allee
M. C., A. U. S., 1912-1944

Col. Charles M. Downs
M. C., U. S. Army, 1900-1945

Capt. Joel Y. Marshall
M. C., A. U. S., 1912-1945

Max Schoenbaum ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1905; on the staff of St. Elizabeth Hospital; died March 27, aged 64, of coronary thrombosis.

Harry Fenton Settle, Kansas City, Mo.; Kansas City College of Medicine and Surgery, 1919; died March 22, aged 64, of coronary disease

William Grant Williams, Bayard, Neb ; University Medical College of Kansas City, Mo, 1907; died March 20, aged 82, of endocarditis and hypertension.

Abraham Zelnigher ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1923; on the staff of the Israel Zion Hospital; died March 14, aged 47, of coronary occlusion.

KILLED IN ACTION

William Sylvanus Allee, Wadsworth, Kan ; Washington University School of Medicine, St. Louis, 1938; interned at St. Luke's Hospital and served a residency at Frisco Employes' Hospital, both in St. Louis; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army on May 14, 1941; prisoner of war of the Japanese; died in the South China Sea Oct. 24, 1944, aged 32, when the ship on which he was being transported was sunk.

Charles McCabe Downs ⊕ Colonel, M. C., U. S. Army, Bloomington, Ind ; born in Casey, Ill., on March 9, 1900; Indiana University School of Medicine, Indianapolis, 1927; Army Medical School and Medical Field Service School in 1930; entered the medical corps of the U. S. Army as a first lieutenant in 1928: promoted through the various grades to that of colonel; in service for eighteen years and in Pacific war zones for three years; in 1945 awarded the Bronze Star for meritorious achievement in connection with military operations on Leyte with the 10th Army Corps, of which he was surgeon; at one time surgeon for the Second Cavalry Division and for the Ninth Armored Division; received the posthumous award of the Army Commendation Medal; killed in action over Mindanao, P. I., June 1, 1945, aged 45.

Joel York Marshall, Alfred Maine; University of Western Ontario Medical School, London, Ont., Canada, 1941; interned at St. Luke's Hospital in Cleveland, where he served a residency; captain, medical corps, Army of the United States; served with an Engineer Medical Corps unit; killed in action in Germany March 15, 1945, aged 33.

May 9, 1947.

Memories of the German Occupation

Bit by bit we are piecing together the experiences of our fellow beings during the German occupation of Norway, and now we have learned how Dr. G. H. Monrad-Krohn, professor of medicine (neurology), played his part. An involuntary testimonial to his patriotism was given him by a former assistant, Dr. Ostrem, one of Quisling's henchmen, who wrote a letter denouncing the professor to the quisling camp. A few days after it was written the professor received a photostatic copy of it provided by the intelligence service of the underground movement. On Jan. 1, 1941 the professor was elected dean of the University of Oslo by the Faculty of Medicine. When the rector of the university and some other professors were arrested and held as hostages, the deans of the various faculties were the only remnant of the original university staff. Clandestine meetings of the deans were held in the professor's office, where plans for the circumvention of nazi rule were devised. In the autumn of 1943 the Germans closed the university and sent several hundred students to prison in Germany. There was now a great danger of a reopened university run by and for quislings. To avoid this, and on the initiative of Professor Monrad-Krohn, the university buildings were turned into hospitals and school rooms for children.

Marriage and Mental Disease

On the paradoxical principle that the busier you are the more time you find for supplementary activities, Dr. Oernulv Oedegaard, medical superintendent of the Gaustad State Asylum near Oslo, continues to make valuable contributions to the psychiatric education of the public and to research. His recent article on the relative importance of heredity and environment with regard to mental disease, published in a Norwegian journal read by laymen, is a stimulating corrective to the fatalism of the hitlerite school of heredity. His recent research into the relationship of marriage to mental disease is based on a study of 14,231 first admissions to Norwegian mental hospitals. He found that the incidence of mental disease was much higher among the single than among the married. He discusses three possible explanations: (1) that a single person who develops mental disease is more readily admitted to a mental hospital, (2) that the subjects of mental disease present certain personality traits which, before its outbreak, act as marriage handicaps and (3) that there are in married life certain factors preventing the outbreak of mental disease. He can find little evidence in support of this last explanation, whereas the second explanation is supported by much valid evidence.

Who Is Best Off, Doctor or Bank Clerk?

The scandal of the inadequate remuneration of doctors holding junior hospital appointments has led to an investigation of the standards of living of members of the community other than doctors in order to draw an instructive comparison. While in Sweden the wage earner selected for this comparison was a typical bus conductor, in Norway the bank clerk has served as a control. He begins to earn when he is 19, whereas a doctor does not do so till he is 27. In the *Journal of the Norwegian Medical Association* for April 1, 1947 an actuary, Herr Gunnar Trier, has calculated how much a doctor ought to earn if his standard of living is to equal that of the bank clerk, after due consideration has been paid to the lean years after the age of 19. He finds that the doctor's annual earning must be at least 13,000 kroner, or $2,600. What we would, of course, also like to know, but are not told, is the actual average earning of our colleagues. What we do know is that as from March 1, 1947 the remuneration attaching to junior hospital appointments is to be scaled upward. But even so these terms are considered far from satisfactory by the medical profession and will assuredly have to be revised in the near future.

Construction of Hospitals

A law was enacted in July 1945 for the creation of a society to construct hospitals in various regions of the country. This law creates a mechanism in which the Public Beneficence, the national treasury and the people participate in the creation of hospitals for the poor. The funds are integrated by (1) money obtained by the government through certain special laws and the general budget of the country, (2) money and property of the Public Beneficence and (3) and (4) money of either private institutions or private parties as given in the nature of investment. The shares are nontaxable. This society has a capital of 300,000,000 Chilean pesos (100,000,000 of the national treasury, 50,000,000 of the Public Beneficence and 150,000,000 of private parties). The amount is progressively increasing. It is in charge of a board of seven directors appointed respectively by the three different constituent parties. The main members of the board of directors now are Drs. Sótero del Río, president, and Benjamin Cid Quiróz, both professors of the University of Chile. As soon as construction of a hospital of the society is finished, the national treasury should rent it with an annual interest of 9 per cent over the cost of construction, to be given to the Public Beneficence for use. The national treasury will give the interest on its shares to the hospitals after completion of their construction. Private holders will have dividends of 8 per cent a year. The hospitals in table 1 are now under construction.

TABLE 1.—*Hospitals Now Under Construction*

Hospital	Number of Beds	Value of Complete Construction
San Juan de Dios (Santiago)	627	$19,362,961.00
Vina del Mar	332	13,152,098.32
Los Angeles	240	15,365,146.00
Arica	150	15,543,452.00
Quillota	194	14,308,102.00
San Vicente (Santiago)	700	40,000,000.00
	2,243	$117,731,739.32

TABLE 2.—*Hospitals To Be Constructed Later*

Hospital	Number of Beds	Approximate Amount
San Francisco de Borja (Santiago)	900	$60,000,000
Chañaral	30	3,000,000
Ancud	50	4,000,000
Loncoche	40	3,500,000
	1,020	$70,500,000

The hospitals in table 2 will be constructed later on in the year.

During 1947 the expenses in hospitals will be about 220,000,000 Chilean pesos, with a total of 2,500 beds. The hospitals will be entirely modern and completely equipped.

Production of Penicillin

A plant for the production of penicillin is regularly working at the Instituto Bacteriologico of Chile at Santiago. This is a semiautochthonous, semiofficial center of scientific research in which vaccines, serums, arsenicals, pentavalents and similar items are prepared for the National Department of Public Health and the hospitals. The production of penicillin is in charge of Chilean technicians. The daily production is 120 million units. Penicillin from the plant is used by the National Department of Public Health and the Hospitals of Beneficence, mainly in the antivenereal campaign.

Cardiologists in Chile

Drs. Pedro Cossio, Antonio Battro and Antonio Taquini, all of the Faculty of Medicine of the University of Buenos Aires and well known Argentine cardiologists, visited the universities and hospitals of Santiago during last October and gave important lectures. Dr. Cossio lectured on cardiac auscultation, on surgical therapy of hypertension and on tachycardia, Dr. Battro on coronary thrombosis and Dr. Taquini on the physiopathologic problem of cardiac dyspnea. They gave clinical bedside lectures to students in the medical departments of the university.

ITALY

(From Our Regular Correspondent)

April 26, 1947.

Academy Centennial

The Academy of Medicine in Turin celebrated its centennial under the chairmanship of Professor Gamna. The old seat, which had witnessed a hundred years of scientific activity, was destroyed by bombardment during the war; consequently the bibliographic patrimony was lost, but the vice president, Professor Luigi Ferrio, reconstructed the history of the academy by patiently investigating the archives and libraries of other institutes in Turin which had not been damaged by the war. This history was published to commemorate the centennial of the academy.

The anniversary was celebrated by a conference with Sir Alexander Fleming, who had been invited for this purpose. He recalled the long research which resulted in the discovery of penicillin and the first clinical applications of the new product. Fleming emphasized that his product should not be considered as a panacea.

Surgical Society

At a meeting of the Surgical Society in Naples under the chairmanship of Professor Cantelmo, Schisano described a case of carcinoma of the uterus in a girl aged 9 who for two years had lost small quantities of blood. Biopsy revealed an epithelioma of the cervix, and total hysterectomy was performed. Postoperative macroscopic and microscopic examination of the specimen proved the diagnosis. For four years after the intervention the patient enjoyed good health.

Radice reported a case of cancer of the vaginal portion of the uterus in a woman aged 19 who was operated on. Death occurred from metastasis within a short time. Niccolo and Greco presented their belief that the anatomicopathologic and the clinical malignancy of a tumor are not always parallel. It may be considered as established that one has to deal with blastomas, which often arise from undifferentiated embryonal elements and which may explain why their microscopic picture is characterized by undifferentiated cells.

Palma discussed the pathogenesis of postanastomotic peptic ulcers based on 23 patients operated on. Interdependence between visceroparietal adhesions and postoperative ulcers may be suggested by the numerous adhesions of the liver, stomach and omentum to the abdominal wall in nearly all cases. In 6 cases the ulcer was localized in the efferent and in 3 cases in the afferent intestinal loop. In 14 cases it was at the new stoma. A silk thread was found in 4 cases at the bottom of the ulcer. Except for the 3 cases of perforation with free peritoneum, death occurred in 3 of the remaining 20 cases, i. e. a mortality of 15 per cent.

The speaker first discussed the factors which other authors consider as contributing to the condition (threads of silk, compressors), but he emphasized that inadequate surgical technic (gastroenterostomy with employment of a longer loop and in a high position) and the visceroparietal adhesions may be responsible in the first order. Various surgeons participated in the discussion of Palma's paper. Bracale stated that some North American authors have demonstrated acute deficiency of one component of the vitamin B complex. The symptoms disappeared and the x-ray examination became negative after these patients were given massive doses of vitamin B.

Intraosseous Anesthesia in Man

Dr. D'Errico tested anesthesia by the intraosseous route with barbituric acid preparations on 19 patients in the surgical clinic of the University of Naples. According to the new technic solution of 2.50 per cent of pentothal sodium is injected into the manubrium of the sternum. It offers several advantages, for instance the possibility of producing anesthesia in persons whose veins are not on the surface, of injecting repeated dose without requiring any apparatus of fixation of the needle and for keeping it passable, and the possibility of easy control during the anesthesia. Untoward reactions, which were related directly to the technic, however, occurred in several cases and consequently D'Errico does not advise its general use for the present.

Deaths

Professor Paolo Fiori, director of the surgical clinic of the university, died in Genoa. Fiori began his university career as an assistant to the Faculty of Medicine of Pavia, dedicating himself to the study of general pathology and endocrinology under the leadership of Professor Giulio Vassale. He then studied clinical surgery and after years of service with other universities was called to succeed his master Professor Giuseppe Tusini in Genoa. Particularly brilliant were his studies on gastric ulcer, experimental hydrosalpinx, gas gangrene and in vitro tissue cultures. His most important surgical contributions dealt with tuberculosis of the cecum, hemolytic splenomegaly and cysts of the spermatic cord. His surgical school is now being continued by such capable pupils as Professors Fedeli and Agrifoglio, the latter of whom has been assigned to university teaching.

Professor Giovanni Boeri, aged 79, formerly director of the medical clinic of the University of Naples, is dead. During the war he suffered the loss of his entire private library of medical papers as the result of bombardment from the air. He was the first physician to reveal in 1914 that amebiasis may in endemic form and without any relation to imported cases from abroad be manifested in the temperate regions of Europe.

Professor Giuseppe Zagari, director, medical clinic, University of Naples, died likewise advanced in years. His studies (1887) on bacterial antagonism were based on the vital competition of micro-organisms and on a new means of prophylaxis against carbuncles; they demonstrated that products of bacterial metabolism may accrue in the culture substance of cholerigenous vibrio; these products of metabolism have an effect on the anthrax bacillus for which then the term "antiseptic" was used by the author, while "antibiotic" is the modern term for this effect. His studies on hydrophobia, carried out in collaboration with Di Vestea, showed that the virus of rabies may reach the nerve centers by the peripheral nerves rather than by the blood vessels.

Zagari contributed to the great Italian treatise of Medical Pathology and Clinical Propedeutics with chapters on rabies, carbuncles, glanders and erysipelas. Only recently he contributed a chapter on septicemia to the Treatise on Internal Medicine by Ceconi.

Correspondence

ALLERGATON—A WARNING

To the Editor:—The Food and Drug Administration desires to warn the medical profession in the Northwest of the presence of a fly-by-night salesman doing business under the trade name of Associated Allergaton Labs., purportedly of 421 Moss Avenue, Oakland, Calif. This salesman, whose name is H. L. Scott, details physicians personally and attempts to sell ampules or vials of a product called "Allergaton," which is represented as a specific for skin irritations such as itching, or in place of liver extract, or for allergic disorders or arthritis.

Samples of this medicine which have been analyzed by the Food and Drug Administration show that it is an alkaline polysulfide solution which causes severe reactions when administered to patients. One patient to whom it was administered by a Seattle physician became violently ill and was confined to bed for two days, as if paralyzed following its administration, and was unable to work for a week after the injection.

There is no such firm as the Associated Allergaton Labs. of Oakland. Mr. H. L. Scott and his associates have been operating recently in the states of Washington and Idaho. They leave no forwarding address or, if they leave one, it is false. They do not operate systematically in any particular area. If any physician is contacted by these promoters we would appreciate his notifying local health authorities or the Seattle office of the Food and Drug Administration in the Federal Building, since the preparation which is being peddled by these promoters is a dangerous one and is capable of causing serious injury when injected, in addition to being useless for the purpose offered.

RALPH W. WEILERSTEIN, M.D., San Francisco.

DETERMINATION OF PROTHROMBIN

To the Editor:—The one stage method for the determination of prothrombin has assumed a steadily increasing importance in the clinical laboratory ever since its introduction in 1935. Unfortunately, much confusion concerning the test still exists, mainly because of unwarranted modifications of the procedure. These, for the most part, have contributed nothing as to increasing its simplicity, accuracy or practicability. It is encouraging to note, however, that many laboratories adhere strictly to my procedure and are reporting exact and consistent results.

The introduction of dicumarol into therapy has made it obligatory, first, that the determination of prothrombin be done correctly, and secondly that the prothrombin of the blood should be reduced to a level which is therapeutically effective. The correct technic for carrying out my method is exceedingly simple. It can be acquired by any qualified technologist in one or two hours, as has been demonstrated repeatedly in my laboratory. One additional hour is required to learn the procedure for preparing thromboplastin from rabbit brain. Technologists thus trained can consistently get a prothrombin time of 11 to 12½ seconds for normal human plasma. This value has now been obtained by me since 1938 and even from thromboplastin made in that year and stored until now. The constancy of this reagent has introduced a degree of accuracy into the study of coagulation which is particularly striking when compared with the notorious inaccuracies that formerly characterized this field.

On the basis of animal experiments as well as by clinical observation it has been found in my laboratory that the critical level of prothrombin at which hemostasis is definitely affected is indicated by a prothrombin time of approximately 19 seconds (equivalent to 30 per cent of normal). This level can be assumed also to be the one at which intravascular clotting is inhibited and therefore the level to which the prothrombin must be reduced for effective therapeutic results. To be sure of the correct level, a reliable thromboplastin must be used, and thus far acetone dehydrated rabbit brain has been the only preparation which has met the requirement for my method.

Particular precaution must be taken if a thromboplastin is prepared from such tissue as lung, which is difficult to free from blood, for such preparations are contaminated with component A, a coagulation factor which I discovered in 1943 (Quick, A. J.: *Am. J. Physiol.* **140**:212 [Nov.] 1943). This has become of practical importance since Owren (Owren, P. A.: *Lancet* **1**:446 [April 5] 1947) has recently reported a hemorrhagic condition in which this factor is presumably diminished. Obviously a thromboplastin contaminated with the very factor lacking in the blood in this condition is entirely unsuited and unsatisfactory. It may be somewhat tedious to fillet a rabbit brain, but it is decidedly worth while, since the product obtained is probably the purest thromboplastin now known and one that has yielded results that have blazed new trails in the assuredly difficult field of blood coagulation.

ARMAND J. QUICK, M.D., Milwaukee.

GENERAL PRACTICE AND RADIOLOGY IN A LARGE HOSPITAL

To the Editor.—Dr. Miller's article on "General Practice in a Large Hospital" in the March 3 issue of THE JOURNAL has been read with considerable interest. He stated that the regular staff of his hospital was organized into four sections: (1) medicine, (2) surgery, (3) obstetrics and gynecology and (4) general practice. Since diagnosis is the cornerstone of modern medical practice, it was rather astonishing to see no mention of departments of radiology or pathology. You are doubtless aware that in the modern nationwide educational program of the Veterans Administration hospitals, the following four departments are stressed: (1) medicine, (2) surgery, (3) pathology and (4) radiology. By giving the two principal diagnostic departments an equal standing with those of medicine and surgery, responsibility is properly assigned and opportunity for advancement in those fundamental specialties increased. This surprising omission was mentioned in a letter to Dr. Miller; he was good enough to inform me that the Mount Carmel Mercy Hospital included a section on pathology and radiology in the department of medicine. It is respectfully suggested that greater progress in sound diagnostic methods would be made if the precedent of the modern Veterans Administration structure were followed, than Dr. Miller's breakdown. General practice may well merit a separate department in addition to the four main ones listed.

L. HENRY GARLAND, M.D., San Francisco.

ACUTE YELLOW ATROPHY OF THE LIVER

To the Editor:—I have read your editorial in the April 12 issue of THE JOURNAL on acute yellow atrophy of the liver. The analysis is an interesting one and it is especially interesting to me that two of the three periods of excessive frequency appeared to have occurred during and after world wars. During these periods an unusually large number of workers were exposed to hepatotoxic substances in industry: The manufacture of trinitrotoluene and the use of chlorinated naphthalenes and diphenyls for insulating cables are examples. While I do not have statistical data as to the extent of this exposure and cannot draw definite conclusions therefore as to its relative importance in the total picture, I believe that it is one of the factors which should be mentioned along with the others in a discussion of this subject. I am bringing this matter to your attention primarily because occupational exposures are so often overlooked in discussions of clinical disease entities.

MAY R. MAYERS, M.D., New York.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Charitable Hospital: Liability for Negligence of Employees in Mistaking Boric Acid for Dextrose.—The plaintiff sued for damages for his daughter's death alleged to have resulted from negligent acts of the servants of the defendant hospital. From a verdict and judgment for the plaintiff, the defendant appealed to the Supreme Court of Errors of Connecticut.

The defendant is a charitable hospital. Its pharmacy, located in the basement of the hospital building, consisted of the pharmacy proper, or workroom, and six rooms containing all sorts of supplies. Boric acid and dextrose, which look alike, were purchased from the same concern, and the containers were of similar cylindric size and shape and were similarly labeled. On the boric acid label, however, were the additional words in small type "for external use only." Both substances were stored on the floor in the pharmacy proper about 4 feet apart. Boric acid is a poison and may be fatal to newborn babies if taken internally. Paula Machnik, a competent pharmacist, was in charge of the pharmacy, and to assist her the housekeeper had assigned Henry Lindner to report to the pharmacy every day between 10 and 12. While in the pharmacy he did what the pharmacist told him to do. He carried packages, washed bottles and filled containers, when directed to do so, with such bulk supplies as talcum powder, green soap, mouthwash, witch hazel, lysol and mineral oil. The various departments of the hospital had so-called supply days (Monday and Thursday for the maternity department) when they sent various containers to the pharmacy in large baskets with order books indicating the material requisitioned. Under hospital routine, in effect at the defendant hospital, newborn infants were given a feeding of 5 per cent dextrose solution. On Thursday, April 6, the dextrose bottle was nearly empty and was sent to the pharmacy to be refilled. It was filled instead with boric acid, the use of which in the feeding formula resulted in the death of 5 babies, 1 of whom was the plaintiff's daughter. The court pointed out that there were two possible bases of liability submitted to the jury: First, was the defendant negligent in the selection of its agents and servants? Second, was it guilty of corporate negligence in failing to provide proper facilities, safeguards and surroundings in the pharmacy? It is the settled law of this state, the Supreme Court emphasized, that a charitable corporation is not liable for the negligence of employees whom it has selected with due care.

The evidence, said the court, as to who filled the bottle with boric acid was a matter of inference from the testimony. The jury reasonably could have concluded that the requisitioned material for the maternity wing on the day in question was supplied by either the pharmacist or Lindner, that in view of her training and experience it was not probable that the pharmacist would have mistaken boric acid powder for dextrose, and that, therefore, in spite of his categorical denial, Lindner did fill it. Negligence on the part of the competent pharmacist would not be a basis of liability, said the court. Assuming that the jury reasonably could have found that Lindner filled the dextrose bottle with boric acid, the same principle would apply, since there was no evidence from which the jury reasonably could have found that the hospital did not use due care in selecting him or in assigning him to do the kind of work for which he was hired under the direction and supervision of the competent pharmacist. The most that the evidence tended to show, the court said, was that the pharmacist improperly directed or permitted Lindner to fill the container. That is far from proving that the corporation or its board of directors failed to use due care in selecting their employees. Furthermore, said the court, the trial court should not have submitted to the jury the question of whether or not the defendant failed to provide proper facilities and safeguards in the pharmacy, since all the evidence introduced was to the effect that the pharmacy was set up in accordance with standard practice. No written rules for its conduct had been prescribed, but there was no evidence that standard practice required this or that their existence would have changed the situation.

Because of errors in instructing the jury, the judgment in favor of the plaintiff was set aside and the case remanded for a new trial.—*Evans v. Lawrence & Memorial Associated Hospitals, Inc., 50 A. (2d) 443 (Conn., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, June 21, page 736.

BOARDS OF MEDICAL EXAMINERS

Arizona: * *Examination.* Phoenix, July 1-2. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

California: *Written.* San Francisco, July 7-10. *Oral.* San Francisco, July 19-20. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Connecticut: *Examination.* Hartford, July 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, July 8. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

Delaware: *Examination.* Dover, July 8-10. *Endorsement.* Dover, July 15. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

Georgia: Atlanta, Oct. 14-16. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Hawaii: *Examination.* Honolulu, July 8-11. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, July 14-16. Sec., Bureau of Occupational Licenses, Dr. S. M. Poindexter, Eastman Bldg., Boise.

Kentucky: *Examination.* Louisville, Sept. 22-24. Sec., State Board of Health, Dr. P. E. Blackerby, 620 S. Third St., Louisville 2.

Maine: Augusta, July 1-2. Sec., Board of Registration in Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

Massachusetts: *Examination.* Boston, July 8-11. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413 E State House, Boston.

Montana: Helena, Oct. 6-8. Sec., Dr. Otto G. Klein, 302 N. Main St., Helena.

New Hampshire: *Examination.* Concord, Sept. 11-12. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

Oregon: * *Examination.* Portland, July 23-25. Applications must be on file on or before July 9. Sec., Miss Lorienne M. Conlee, 608 Failing Bldg., Portland.

South Dakota: * Pierre, July 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

West Virginia: *Examination.* Charleston, June 30, July 1-2. Commissioner, Public Health Council, Dr. Newman H. Dyer, State Capitol, Charleston 5.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: Sept. 16. Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Sept. 17-18. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

District of Columbia: *Examination.* Washington, Oct. 20-21. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6012 E. Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, Nov. 1. Final date for filing application is Oct. 16. Sec., Dr. W. M. Emmell, University of Florida, Gainesville.

Iowa: Des Moines, July 8. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 10-11. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

Nebraska: *Examination.* Omaha, Oct. 7-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Department of Health, Room 1009, State Capitol Bldg., Lincoln 9.

Oklahoma: The date for the next examination has not been set as yet but will be sometime in the spring of 1948. Sec., Dr. Frank Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Sept. 6. Final date for filing application is Aug. 20. Sec., Board of Higher Education, Basic Science Examining Committee, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: *Examination.* Aug. 13. Chief, Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Wisconsin: *Examination.* Madison, Sept. 27. Sec., Mr. William H. Barber, Watson and Scott Streets, Ripon.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. Obstetrics and Gynecology, St. Louis

Pregnancy in Patient with Hypertensive Disease.—Chesley and Annitto collected from the files of their hospital records of women in whom recorded blood pressures before the twenty-fourth week of gestation permit the diagnosis of "hypertensive toxemia." In the thirteen year period from October 1931 through 1944 there were 301 pregnancies occurring in 218 women in whom the diagnosis of hypertensive disease could be established. Fetal loss in prior pregnancies was 35 per cent, in first hypertensive pregnancy 38 per cent, in subsequent pregnancies 40 per cent. Fetal loss increased with higher initial blood pressure, second trimester rises in blood pressure, higher pressures near delivery, decreased renal function, proteinuria and superimposed toxemia. Of 47 sisters of these hypertensive patients who were delivered at the hospital 45 per cent had at least one toxic pregnancy. Nearly 40 per cent of the hypertensive patients showed drops in the blood pressure in midpregnancy. Proteinuria of some degree occurred in half of the pregnancies. Renal function was normal in 93 per cent of the pregnancies. Premature separation of the placenta occurred in 5.6 per cent of the pregnancies. There were 13 immediate and late puerperal deaths among the 301 women. Of these 13 fatalities 8 were probably associated with hypertensive disease, while 5 were attributable to intercurrent causes.

Problem of Talcum Glove Powder.—As the result of studies on scars Douglass believes that many cases exhibiting postoperative incisional pain and tenderness may be charged to inflammatory reaction generated by magnesium silicate crystals deposited by the gloved hands or drains at the time of operation. Until a substance is found that does not have the disadvantages of magnesium silicate, the author advises that only enough magnesium silicate powder be applied to the inside of the gloves before dry sterilization to avoid the adhesion of their surfaces during the sterilizing process. Cream of tartar is applied to the hands in small quantities, enough to assist the hands into the sterile gloves. All powder remaining on the external surface of the gloves is removed by washing through two basins of sterile water.

Roentgenologic Findings in Myasthenia Gravis.—Good made a study of 100 consecutive cases of myasthenia gravis that had been observed at the Mayo Clinic since 1941. In 17 of these roentgenologic examination disclosed a tumor in the anterior mediastinum. Exploratory operation was performed in 11 cases and necropsy in 3 other cases. Microscopic examination in all but 1 case demonstrated that the tumor originated in the thymus. Thymic tumors found in this series have been grouped into two classes according to the ease of roentgenologic recognition. One type is well defined and is easily seen in all roentgenograms. The other type is plaque-like in shape and is easily overlooked. In order not to overlook thymic tumors the recommended roentgenologic procedure consists in roentgenoscopy and lateral roentgenograms of the thorax as well as the more customary stereoscopic roentgenograms made in the frontal projection.

Myelosclerosis with Leukoerythroblastic Anemia.—Sussman presents the histories of 9 patients in whom myelosclerosis was demonstrated roentgenologically in the presence of leukoerythroblastic anemia. This type of myelosclerosis is usually characterized by an increase of megakaryocytes and platelets and for this reason it is sometimes designated as megakaryocytic leukemia. Differentiation from other conditions associated with myelosclerosis is not difficult. Although the disease may be chronic, there is usually progression into frank leukemia as seen at postmortem examination.

Curare for Infants and Children.—Smith used curare in the treatment of 41 infants and children who ranged in age between 20 hours and 30 months and in weight between 4½ and 29 pounds (2 and 13 Kg.). Intocostrin was used in 8 cases and d-tubocurarine chloride in 33 cases. These curare preparations were given intravenously to 15 patients, intramuscularly to 21 and by other routes to 5. The initial dose varied from 4 to 44 units. The supplemental dose ranged from 2 to 20 units. The total dose varied from 0.16 to 3.6 units per pound. The interventions included Rammstedt's operation, appendectomy, splenectomy and 15 other intra-abdominal procedures, also herniorrhaphy and repair of diaphragmatic hernia. Atropine was given as the sole premedication to 9 patients. Two other patients had atropine and morphine, 2 had atropine and phenobarbital sodium and 28 received no premedication. No difficulty was encountered when atropine was not administered. The operative conditions and postoperative results were excellent. In view of the conclusive demonstration that curare has no significant central depressant or analgesic action, the author believes that curare should always be employed in combination with agents capable of producing analgesia or anesthesia.

Gamma Globulin from Large Pools of Blood in Infectious Diseases.—Stokes points out that the protein fraction of blood plasma termed gamma globulin has assumed a greatly enhanced significance as a result of the fractionation of plasma and of the pooling of plasma for fractionation from hundreds of thousands of blood donors under the system of blood collection inaugurated by the American Red Cross. The large size of the plasma pools tends to assure a surprisingly uniform titer of antibodies against the infectious agents endemic to the geographic area in which the blood donors reside. Gamma globulin from fractionated pools of plasma concentrates and preserves such antibodies in a readily usable form, which thus far apparently has been free from the danger of serum hepatitis. The amount of specific protective antibodies in the gamma globulin and their effectiveness against various epidemic diseases obviously differs. The author discusses the value of gamma globulin in measles, mumps, infectious hepatitis and poliomyelitis.

Antihemophilic Globulin.—Minot and Taylor say that in addition to decreasing the coagulation time of hemophilic blood by the use of globulin preparations progress has been made in the development and utilization of thrombin preparations for the control of hemorrhage. The introduction of such hemostatics has materially lowered the dangers attendant on surgical operations on hemophilic patients.

W. S. Priest, J. M. Smith and C. J. McGee, with technical assistance of Irene Gilbert and Dolores Kenney.—p. 333.

Acute Hemolytic Streptococcic Sore Throat.—Rantz and his co-workers described in an earlier paper the initial phase of acute sore throat caused by group A hemolytic streptococci in young men. They now report the subsequent events which occurred in this group of patients during the initial phase of the disease and the suppurative complications that followed. The degree and duration of fever and the initial erythrocyte sedimentation rate were poorly correlated with the degree of physical abnormality of the throat and neck. A more prolonged febrile illness occurred if a cutaneous rash was present. The initial leukocyte count varied with the severity of the acute disease. A rash occurred only when the infecting streptococcus was of type 3, 17, 19 or 30. The disease caused by six serologic types was otherwise similar. Several therapeutic regimens involving the administration of sulfadiazine and penicillin alone and in combination were utilized. None effectively terminated the disease or consistently eradicated the hemolytic streptococcus from the nose and throat.

Bronchogenic Adenoma.—Fried points out that bronchogenic adenoma is the commonest benign bronchial tumor, comprising from 6 to 12 per cent of all bronchial neoplasms. It is prevalent in patients in the third and fourth decades and occurs oftener in women and more frequently on the right side. It occurs in bronchi accessible to inspection with the bronchoscope. Therapy applied in the early stages eradicates the disease, while dilatoriness is fraught with dangerous complications, such as putrid abscess and bronchiectasis, pneumonitis and empyema.

Penicillin Therapy of Subacute Bacterial Endocarditis.—Priest and his associates review the end results obtained in 34 unselected cases of subacute bacterial endocarditis in which the patients were treated with penicillin. Twenty-two are alive and free from evidence of the disease from thirteen to thirty-five months after completion of treatment. Duration of the disease ranged from one and a half to fifty-two weeks before admission. Streptococcus viridans predominated as the offending organism, but six other organisms were encountered. Administration of penicillin in isotonic solution of sodium chloride by continuous intravenous drip was found superior to intermittent intramuscular injection in the maintenance of constant adequate blood levels and of the patient's comfort. To increase the dose of penicillin seems simpler than to use para-aminohippuric acid or diodrast to retard the rate of excretion from the kidneys. No clinical or histologic evidence was found to favor the use of anticoagulants. The danger of fatal hemorrhage suggests caution in their use. Adequate daily dosage over a sufficiently long period is the most important single factor in treatment. With the use of the continuous intravenous drip the minimal efficacious dose is 500,000 units per day, with administration of 1,000,000 to 2,000,000 units per day or more if clinical criteria dictate or if the disease is of over twelve weeks' duration. If intermittent intramuscular injection is the only feasible method, minimal doses of 100,000 units at ninety minute intervals are recommended. Treatment should be continued for not less than four weeks.

Associated Systemic Factors in Retinitis Pigmentosa.—Givner and Bruger studied the basal metabolism, pressure and chemistry of the spinal fluid, vitamin content of the blood plasma, hepatic function, serum cholesterol, creatinine and creatine in the urine, pupillary reactions, the auditory apparatus and the capillaries of 14 patients with retinitis pigmentosa. The basal metabolic rate was mostly normal or slightly below. Eleven patients had creatinuria. This series included 8 males and 3 females. The spinal fluid pressure was increased in 3 of 12 patients, but readings in most of the other patients bordered on the upper limit of normal rather than falling at the lower levels. *In 3 of 12 patients the total protein content of the spinal fluid* was increased. Hepatic damage was not demonstrable in any of the 12 patients investigated. The fasting ascorbic acid content of the plasma was reduced in 7 of 9 patients. Vitamin A studies on the serum of 7 patients gave normal values. In 11 patients pupillographic studies showed tonohaptic reactions and other evidences of diencephalic disorders. Analysis of the blood for retention of urea nitrogen and determination of the specific gravity of the urine after administration of pitressin failed to reveal measurable impairment in the renal function of 13 patients. Physical examination, including neurologic studies, gave essentially normal findings except for the high incidence of high-arched palate and nerve deafness, as revealed by audiometric tests. Seven of 8 patients thus studied revealed impairment of hearing. Two patients were deaf-mutes. Examination failed to reveal abnormalities in the capillaries of the finger bed.

Effect of Testosterone Propionate on Metastases of Carcinoma of Breast.—Herrmann and Adair administered testosterone propionate in doses which influence osseous metastases to 3 patients with soft tissue metastases. These doses proved ineffective. One patient showed temporary regression of the lesions. Massive daily doses of the androgen were administered to 3 other patients. One of these patients showed striking regression of the lesions. The administration of large amounts of androgen apparently had no effect on the subsequent response of lesions to roentgen therapy. During the time testosterone propionate was administered, there was in every patient, except 1, an increase in weight which was lost subsequent to the withdrawal of the androgen. Facial hirsutism, deepening of the voice, acne and an increase in libido were encountered in all the patients.

Chronic Cystic Mastitis and Sterility.—According to Morton, chronic cystic mastitis is the result of a relative or absolute excess of estrogens producing abnormal proliferation of the mammary ducts. Although the estrogenic level may be within normal limits, pregnandiol has been shown to be low or absent. Review of the literature reveals evidence indicating the endocrine origin of chronic cystic mastitis, but no suggestion of a relationship between this condition and infertility could be found. In 24 infertile women with mammary dysplasia there was a parallelism between the occurrence of chronic cystic mastitis and an absent or poorly developed secretory endometrium. This indicates that the endometrial and mammary abnormalities are both manifestations of disturbed estrogen-progesterone balance. Both this group and a second group of 15 patients complaining of mammary symptoms alone responded to treatment with chorionic gonadotropin, with improvement or disappearance of the chronic cystic mastitis. Of the 24 infertile women 8 subsequently became pregnant.

Pathogenicity and Antigenicity of Strains of Herpes Simplex.—Florman and Trader made comparative studies of pathogenicity and antigenicity of four strains of herpes simplex in order to investigate some of the differences which may exist between strains of a single viral species. Mice, rabbits, guinea pigs, white rats, hamsters, cotton rats and chick embryos were observed after inoculation of mouse brain emulsions by various routes. Although herpes simplex is a pantropic virus, differences between strains are accentuated by certain tests. Thus, death of the majority of animals following corneal infection of the rabbit or intranasal inoculation of the cotton rat can be used to indicate strains with prominent neurotropic tendencies, while severe local reactions after intradermal injection of the guinea pig are indicative of dermatotropism. These distinctions probably hold only for the particular species of animals and routes tested, as the strain which was most dermatotropic in the laboratory was the cause of fatal encephalitis in a human being. It is not known whether these differences in potentiality of herpes strain are of epidemiologic significance.

Erythema Multiforme Exudativum.—Thirty-three cases of erythema bullosum malignans of the pluriorificial type occurred at Willard Parker Hospital for Contagious Diseases between 1932 and June 1946. Of the cases selected for study by Costello, 17 are reported in detail with one complete postmortem examination. Destructive lesions of the cornea and conjunctiva terminating in grave ocular sequelae such as panophthalmitis and blindness were the most urgent features which required constant ophthalmologic care. Vaginal and urethral stenosis occurred in 2 cases. Three patients died and 1 became blind. An upper respiratory onset occurred in over half the patients. A virus cause is suspected. The relatively large number of patients suffering from this disease were admitted to Willard Parker Hospital for Contagious Diseases because of the resemblance of this dermatosis to such contagious diseases as chickenpox, measles, influenza, agranulocytic angina and pemphigus. The treatment is symptomatic. Penicillin was administered to 2 patients and aided in their recovery.

Systematized Amyloidosis with Macroglossia.—Brunsting and MacDonald present the record of 4 patients which illustrates the characteristic signs and symptoms of the rare syndrome of systematized amyloidosis of the skin and muscles with widespread involvement of the skin and with macroglossia. In 2 instances necropsy revealed extensive deposits of amyloid in the heart and the musculature of the gastrointestinal tract, while the liver, spleen, kidneys and adrenals were spared, for the most part. The relation between amyloidosis and multiple myeloma is brought out by the demonstration of Bence Jones proteinuria and of abnormal cells of plasmocytoma in the bone marrow. Emphasis is placed on biopsy of the skin, tongue and skeletal muscles; vital staining of amyloid in the skin by the subcutaneous injection of congo red; examination of the urine for Bence Jones protein as well as of the blood proteins, including the albumin-globulin ratio; roentgenograms of the bones, and sternal aspiration in search of plasmocytoma in the bone marrow. The evidence presented confirms that amyloidosis and myeloma are part of the same systemic process, the origin of which remains obscure.

Synthetic Folic Acid in Pernicious and Related Anemias.—According to Vilter and his associates folic acid in doses of 10 to 15 mg. daily or 30 mg. three times a week given orally maintained 21 persons with pernicious anemia in apparent hematologic remission for one year. Three patients with pernicious anemia whose treatment was begun during a relapse responded satisfactorily. Folic acid given orally controlled the manifestations of sprue in 2 persons for one year, nutritional macrocytic anemia in 1 person for seven months and macrocytic anemia secondary to ileosigmoidostomy in 1 person as/or more effectively than liver extract. Folic acid in doses of 10 to 50 mg. daily did not prevent the development of neurologic signs, and doses of from 100 to 500 mg. daily did not stop the progression of the neurologic symptoms, when liver extract promoted rapid improvement. These observations suggest that an unknown factor or factors in liver other than folic acid are essential for maintaining the integrity of the central and peripheral nervous systems in persons with pernicious anemia. Folic acid cannot be considered satisfactory or complete treatment for pernicious anemia and should not replace potent liver extract in the routine treatment.

Effects of Maternal Undernutrition on Newborn Infants.—Smith points out that during the six or seven months which preceded the liberation of northwestern Holland in May 1945 a state of severe undernutrition was prevalent. The effects of this nutritional crisis on the infant at birth were investigated especially in the cities of Rotterdam and The Hague. During the period, and apparently because of the low food supply, about 50 per cent of urban women became amenorrheic and presumably infertile. The birth weights of infants decreased and rose after restoration of food in a manner indicating that fetal weight gain is particularly related to the maternal diet of the last half or last trimester of pregnancy. Significant decline in length also occurred but was less clearly apparent than the change in weight. No conclusions could be drawn with regard to the frequency of abortion, while that of prematurity was insignificantly increased. Stillbirth was definitely not increased, nor was neonatal mortality among infants born in hospitals. A slight but statistically insignificant increase in malformations did occur. Several of these results are widely at variance with those of other studies, so that great caution must be used in evaluating the maternal-fetal aspects of nutrition.

Children Born During Siege of Leningrad.—Antonov states that during the severe hunger period in the first half of 1942 the stillbirth rate rose to 5.6 per cent, twice the normal figure; the rate of premature births reached the unusually high figure of 41.2 per cent. The average weight of infants born at term in the first half of 1942 was 500 to 600 Gm. less than normal. The physiologic loss of weight continued longer than usual; the average loss exceeded the usual figure. The morbidity of the newborn was unusually high, 32.3 per cent, owing in part no doubt to their low vitality. The most frequent diseases were scleredema, sclerema and pneumonia. The mortality of the newborn was unusually high, 9 per cent for those born at term and 30.8 per cent for those born prematurely. Antonov does not contradict the prevailing opinion that the fetus behaves like a parasite in the mother's body, but on the basis of this material he concludes that the condition of the host, the mother's body, is of great consequence to the fetus, and that severe hunger of the mother affects decidedly the development of the fetus and the vitality of the newborn child.

Airblock in Newborn Infants.—Salmon and his co-workers are concerned with the condition produced by escape of air from the normal respiratory pathways into tissues in which it is not normally present. They believe that this condition, which has been designated as airblock, is frequently unappreciated at necropsy. Methods of postmortem examination used in the newborn period should include measures to detect the presence of aberrant air. In newborn infants interstitial pulmonary air can produce pneumothorax by either of two mechanisms: (*a*) rupturing the visceral pleura directly or (*b*) first producing mediastinal emphysema and then rupturing the mediastinal pleura. The possibility of pulmonary interstitial emphysema producing air embolism needs further investigation, as does also the effect of pulmonary interstitial emphysema on the heart. Factors which may lead to the production of pulmonary interstitial emphysema are not infrequently present in the newborn period. The incidence of pulmonary interstitial emphysema in this period is undoubtedly higher than is commonly believed.

Prevention of Postoperative Pulmonary Embolism.—Reviewing 52 fatal cases of postoperative pulmonary embolism, Evans and Boller found that the greatest number occurred in patients 50 to 60 years of age. Fifty-four per cent of the deaths occurred after extensive pelvic or lower abdominal surgery or both. This poses the question of routine prophylactic administration of heparin in Pitkin's menstruum and dicumarol shortly after such major surgical procedures. The variability of the signs and symptoms associated with pulmonary embolism emphasizes that a thrombotic process should be suspected postoperatively in every case of fever or tachycardia or both. Fifty-two per cent of the initial pulmonary emboli occurred between the sixth and sixteenth postoperative days, although a sufficient number occurred before and after that period to make one continuously on the alert for trouble. Routine examination of the legs postoperatively is required for evidence of phlebothrombosis. In 85 per cent of the 52 fatal cases, some preventive measure was indicated by premonitory signs, usually in the form of elevated temperature or tachycardia or both occurring a sufficient time before the fatal embolism to allow adequate therapy to be administered.

Rheumatic Mitral Valve Disease Without Cardiac Enlargement.—Epstein asserts that loud apical murmurs diagnostic of mitral valve disease may exist in the absence of cardiac enlargement or changes in the silhouette of the heart, just as it is possible for pronounced cardiac enlargement to be present with minimal and often misinterpreted murmurs If the murmurs are characteristic, the diagnosis of mitral valve disease must be made even in the absence of radiologic criteria Conversely, if there is any enlargement of the heart, the conclusion that organic heart disease is present must be reached It should be recognized by both the radiologist and the clinician that in mitral valve disease there may be no visible alteration in the x-ray appearance of the heart, just as murmurs may be absent or atypical.

Gastritis in the Toothless.—Reviewing the histories of 3,684 patients with gastrointestinal disturbances, Rodriguez-Olleros found 168 who had extensive deficiencies of dentures which made proper mastication impossible. Nearly half of these patients, or 48.8 per cent, had primary gastritis, whereas of the *remaining 3,516* patients with efficient mastication only 6.1 per cent had gastritis. The author believes that the part played by mechanical irritation of the stomach produced by deficient mastication is more important in the genesis of gastritis than the medical literature of today suggests.

Coccidioidomycosis and the Chest Roentgenogram.—Clark says that from 70 to 80 per cent of the people who live in certain sections of western Texas, New Mexico, Arizona and southern California are found to have a positive coccidioidin skin test indicating active or inactive coccidioidomycosis infec*tion. A sizable percentage of the transient population to these* areas will likewise become infected. The great majority of infections are mild and self limited and involve the lungs and associated lymph nodes Most of the residual lesions are visualized on the roentgenogram and are confused with tuberculosis, cancer, Boeck's sarcoid or pulmonary fibrosis due to other agents The greatest difficulty arises in the differentiation of tuberculosis and coccidioidomycosis It is important to make a differentiation, because inactive lesions of coccidioidomycosis can be disregarded as a cause of future disability whereas the lesions of tuberculosis require observation and treatment. It is frequently impossible to differentiate a chest lesion in which both the coccidioidin and tuberculin skin tests are positive. Sputum should be studied for the tubercle bacillus and the presence of Coccidioides immitis. If the patient is not raising sputum, a number of cultures for the tubercle bacillus should be made of gastric washings. If no organisms are found, the character of the chest lesion may be suggestive of coccidioidomycosis.

Exophthalmos and Orbital Tumors.—Forbes describes 8 cases of unilateral exophthalmos due to orbital tumors. The tumors causing the proptosis were a lipoma, an extraorbital squamous cell carcinoma, a pyocele, a mucocele, a muscular hypertrophy or tumor associated with an exophthalmic goiter with two thyroidectomies, a true primary pseudotumor in all probability, and in 2 instances a cavernous hemangioma. The author describes a method of delivering a large hemangioma *en masse* and directs attention to the use of the electric saw for resection of the bony wedge in the Kronlein operation. Refractive changes may be of diagnostic value in cases of retrobulbar tumor. This was proved in 2 of the reported cases.

Total Intravenous Alimentation.—Bigham and his co-workers investigated protein metabolism during periods of total intravenous feeding in more than 25 patients. The group has included normal persons, patients with acute infections such as malaria and ulcerative colitis, degenerative diseases and patients before and after major surgical operations. The mixtures have consisted of "amigen," glucose, salts, water and vitamins. As an adjuvant measure in preoperative and postoperative therapy in certain types of cases the procedure has afforded the surgeon a relaxed empty bowel easy of handling. The postoperative course has been unusually benign and free of distention in every instance but 1. Except where there has been an irritative lesion of the intestine, as in ulcerative colitis, stools usually cease under this therapy in two to three days.

Benign Cavernous Hemangioma of Spleen.—Hodge and Wilson found only 31 cases in the literature that appear to represent true benign cavernous hemangioma of the spleen. Their patient was a Negro woman aged 35, who was admitted to the hospital with a complaint of an upper abdominal mass of four months' duration, with rapid increase in size in the last three weeks. The patient was operated on and a tumor weighing 13,130 Gm. was removed. She recovered. The diagnosis of benign cavernous hemangioma may be extremely difficult. It was an incidental finding in 11 of 12 necropsy cases. In the other case there was rupture of the lesion with death. In the 19 patients treated surgically 3 had a spontaneous rupture with serious hemorrhage into the abdominal cavity. A diagnosis of perforated gastric ulcer was made in 2 and appendicitis in 1. The other surgical cases presented the following combinations of signs and symptoms: abdominal mass or splenomegaly, pain, dyspnea, dysphagia, gastrointestinal disturbances and anemia. Splenic hemangioma should be suspected in patients with splenomegaly unrelated to a general disease process. When rupture occurs, shock, pain and signs of generalized peritoneal irritation are usually present. Shock must be combated, and immediate operation is imperative.

Cystadenoma of the Pancreas.—Benson and Gordon report the history of a woman aged 65 which illustrates the efficacy of surgical excision of a cystadenoma of the pancreas. They review a series of 28 cases collected from the literature. Cystadenoma of the pancreas is a benign, multilocular, cystic adenomatous neoplasm which most often originates from the tail or body of the pancreas. Clinically this tumor is characterized by a slow growth, absence of early symptoms and later development of a palpable tumor, upper abdominal pain and weight loss. Pancreatic cystadenomas occur much more frequently in women than in men (ratio 8:1). Complete surgical removal of the tumor is the treatment of choice.

Arterial Damage in Clostridial Wound Infections and Gas Gangrene.—Experience with the treatment of clostridial wound infections occurring among Chinese and American troops in North Burma convinced North of the importance of differentiating between those with major vascular damage and those without such injury. Gas gangrene is unlikely to develop unless the integrity of the main arterial blood supply is impaired either by the initial trauma or secondarily by such factors as tension within closed tissue compartments or external constriction by improperly applied plaster casts. There were 32 cases of true gas gangrene, representing an incidence among combat wounded of 7 cases per thousand casualties. The mortality in this group was 31.3 per cent, and no one survived without a major amputation. Wound infection by clostridial organisms in which the main blood supply of the part remains intact presents a much more favorable prognosis. In 37 such patients none developed gas gangrene, none required amputation and only 1 died. *Limited surgical excisions which eliminate anaerobic conditions from the wound are adequate for this type of case.*

Penicillin in Craniocerebral Injuries.—Abbott records observations on the use of penicillin in 62 cases of severe open (compound) craniocerebral injuries which were studied in the Southwest Pacific Theater of Operations. Included in this group were 19 cases in which one or more cerebral ventricles had been exposed or perforated. Penicillin was placed in the ventricles of each of these patients in doses of 25,000 to 50,000 units. In no instance were untoward toxic or irritative reactions observed. In 1 case 100,000 units of penicillin was placed in the cisterna magna in the treatment of pneumococcic meningitis. Only transitory and mild untoward symptoms resulted, and recovery ensued.

Acute Coronary Insufficiency.—Master and Auerbach emphasize that there are several acute coronary artery diseases rather than one. They are divided into two main divisions: (1) acute coronary insufficiency and (2) acute coronary artery occlusion. The concept of acute coronary insufficiency as a clinical entity is new. The precipitating causes are those of the ordinary episode of angina pectoris. The myocardial anoxia may be severe and prolonged. There is a disproportion between the demands of the myocardium and the oxygen or blood available to it. Diffuse, focal, disseminated areas of necrosis may be found in the subendocardium and the papillary muscles. There is no involvement of the pericardium or endocardium. The *treatment is prophylactic, preventive, and it may be life saving.* The prognosis is better than in acute coronary artery occlusion, which is a sudden complete closure of the vessel and results from advanced arteriosclerosis in some portion of an artery. The infarct is massive, involving endocardium and pericardium, with frequent mural thrombosis on the inner surface of the heart and subsequent embolization, and with frequent pericarditis. Treatment is of no avail.

Penicillin Therapy in Relapsing Fever.—Shaul and Saferstein report 4 cases of North African fever, which were treated with penicillin. Two patients did not have relapses. A third patient, who might have escaped a relapse if a longer initial course of penicillin had been given, received a second course and was cured, as was the fourth patient treated during the first relapse. The optimum therapeutic amount of penicillin appears to be between 1,560,000 and 2,800,000 units given in 40,000 unit doses every three hours intramuscularly.

Nodule Formation in Rheumatic Disease.—Kersley and his associates kept separate clinical records and biopsy reports on all cases of rheumatic or plorheumatic disease in which nodules were palpable and later classified them clinically, comparing their clinical diagnosis with the findings of the pathologist. Twenty-seven cases have been so examined. According to the clinical and pathologic c the authors differentiate five groups: (1) gout, (2) typical rheumatoid arthritis, (3) rheumatic fever, (4) fibrositis and (5) fus nodules in the absence of signs of rheumatic disease. The study emphasizes the diagnostic value of biopsy of nodules in rheumatic diseases.

Ammi Visnaga for the Anginal Syndrome.—According to Anrep and his associates Ammi Visnaga, known in Arabic as "Khella," grows wild in the eastern Mediterranean countries and in Arabia. The decoction of its dried seeds is frequently prescribed by local physicians a diuretic and antispasmodic in cases of ureteral stones. Of the several crystalline substances isolated from the seeds the most important is khellin ($C_{14}H_{12}O_5$). The authors investigated the action of khellin on the cardiovascular system in dogs with special reference to the coronary circulation and the heart muscle and they also studied its action clinically on patients with angina pectoris and coronary thrombosis. The substance was found to be an effective vasodilator with a selective action on the coronary vessels, so that coronary flow was increased by doses insufficient to lower the general blood pressure. Continuous treatment by the oral or intramuscular routes or by the two combined gave favorable results in 35 of 38 cases of angina pectoris. The drug was given continuously for several weeks 8 patients after coronary thrombosis and appeared to act favorably.

New Sign of Dissecting Aneurysm of Aorta.—Nissim discusses improvement in the recognition of dissecting aneurysm of the aorta. He reviews clinical and postmortem observations on a man aged 71 in whom a new sign of the disease is described. There was a difference between the right and left carotid pulsations; they were reduplicated on the right and single on the left, without a coexisting noticeable difference in the intensity of the pulsations on the two sides. There were two almost equal beats in quick succession on the right carotid for every single beat on the left. The explanation must lie in the difference of the rate of propagation of the pulse wave through the lumen of the artery and through its dissected coats where the blood was probably partly clotted. At necropsy this was the only pathologic finding that could account for it. The full significance of this sign was not realized until then.

Poisoning with Preparation of Iron, Copper and Manganese.—Forbes discusses the toxicology of the salts of iron, copper and manganese and describes 2 cases of fatal acute poisoning due to a proprietary preparation containing ferrous sulfate, manganese sulfate and copper sulfate. Results of the chemical analysis of the liver and the bowel and its contents are given in each case. A short series of animal feeding experiments is described, proving that the ferrous sulfate is the noxious ingredient in the preparation concerned.

Diphtheria in a Highly Immunized Community.—The chief points brought out in the outbreak described by Fanning are (1) the possibility of an alarming outbreak of diphtheria in a highly immunized community (94 per cent previously immunized, 80 per cent Schick negative), (2) the failure of previous immunization to protect against a severe attack in certain cases and (3) the occurrence of a high proportion of cases among Schick-negative reactors. The outbreak occurred in a private day school for girls. On the basis of observations in this outbreak the author emphasizes the necessity for repeated doses of antigen during the whole of school life. The interval suggested between doses is three years. The limited value of the Schick test as a measure of immunity is pointed out.

Penicillin in the Treatment of Diphtheria.—De and his associates of the Medical College Hospitals of Calcutta review observations on 27 cases of diphtheria in which only penicillin was used for treatment. Sixteen of the patients were bacteriologically positive and 11, though bacteriologically negative, were clinically typical cases of diphtheria. Twenty were early and 7 moderately severe. Recovery occurred in all cases without developing complications; the temperature was normal within three days, the throat swabs became negative within three to seven days, and the patches disappeared within two to five days. The author thinks that this small group of cases does not permit assessment of the value of penicillin, the less so since only early or moderately severe cases with slight toxemia were selected. Penicillin cannot replace antitoxic serum in severe cases of diphtheria where immediate neutralization of toxin is imperative.

*Medical Indications for Extirpation of Spleen: Results. A. Dirix and J. Vandenbroucke.—p. 97.
Sensitizer for Therapeutic Action of Digitalis Substances. H. Handovsky.—p. 104.

Medical Indications for Splenectomy.—Dirix and Vandenbroucke review observations on 26 cases in which splenectomy was performed. Five patients had thrombopenia and 8 had hemolytic icterus which was either congenital or acquired. Other conditions for which splenectomy was done included Banti's syndrome, thrombophlebitis of the splenic vein with congestive splenic tumor, paroxysmal hemoglobinuria of the Marchiafava type, hemolytic anemia of unknown origin, splenomegalic cirrhosis, congestive tumor of the spleen presenting the clinical picture of splenic panmyelophthisis and malignant tumor of the spleen. There were 7 fatalities among the 26 patients. The results were favorable in the patients with essential thrombopenia, hemolytic icterus and thrombophlebitis of the splenic vein with congestive tumor. In the group with Banti's syndrome, in which the splenic factor is not entirely clear, splenectomy was a failure and served to increase the mortality rate. In the isolated case of splenic panmyelophthisis the results were favorable.

*Treatment of Arterial Hypertension with Complete Dechloridation. H. Chabanier and C. Lobo-Onell.—p. 85.
Occupational Pathologic Syndrome. M. Gautrelet and J. Sterboul.—p. 90.

Dechloridation for Arterial Hypertension.—Chabanier and Lobo-Onell treated 9 patients, 3 men between the ages of 45 and 62, and 6 women between the ages of 43 and 52, with arterial hypertension as the only manifestation of nephroangiosclerosis with complete dechloridation for four to thirteen months. The hypertension was reduced to normal in 2 patients, a partial reduction resulted in 5 patients and failure occurred in 2 patients. The hypertension was reduced considerably in a woman aged 32 with chronic diffuse glomerulonephritis who had been placed on a salt free diet for six months. Some of the patients did not interrupt their occupational work, and the rest were able to resume their occupation in the course of treatment. The effect of the complete dechloridation has been slow and progressive as compared to that of surgical treatment of hypertensive syndromes. Dechloridation has been effective while hypotensors failed. Untoward reactions did not develop in spite of prolonged complete dechloridation. This treatment is suggested particularly for patients over 40 years of age with nephroangiosclerosis in the premalignant or prenephritic stage and for the chronic or vascular stage of diffuse glomerulonephritis.

Regulatory Apparatus at Vascular Pole of Corpusculum Renis.—Schloss demonstrates that in rats it is possible to produce hypertension by compressing one or both renal arteries with a clamp. If the throttled kidney is removed at the onset of hypertension the blood pressure decreases to normal values. Retention of water is accompanied with a striking decrease in blood pressure. Both of these manifestations apparently are caused by circulatory insufficiency. The terminal retention of urea in some rats is due to functional disorders in the renal tubules of the kidney which has not been blocked. Hypertension can exist without tissue changes in the blocked kidney, but atrophic changes begin in this kidney usually after a few days. Discussing the changes observed in the granulated epithelioid cells of the afferent arterioles of the blocked and unblocked kidney, the author says that these so-called e-cells are probably not essential for proper renal function. He was unable to detect in rats any connection between the e-cells and the hypertension due to constriction or any other evidence that e-cells can produce the pressor substance "renin." On the other hand, the renal tubules seem to play an important role in the production of "renin."

Beware of Phenothiazine. D. P. R. Keizer.—p. 424.
*Peculiar Localization of Pain in Chronic Cholecystitis. N. J. Teljer. —p. 428.

Epidemiology of Acute Anterior Poliomyelitis.—Hemmes analyzes some controversial problems concerning the spread of poliomyelitis on the basis of observations made in the Netherlands during 1923 to 1945. He denies the occurrence of "stille feiung" (silent immunization). He advances the hypothesis that the virus which is excreted by human subjects does not infect others directly but has one or several intermediate hosts, which in turn may perhaps contaminate foodstuffs.

Peculiar Localization of Pain in Chronic Cholecystitis.—Teljer's observations were made on himself. For months he had pains in the right leg in the region of the sciatic nerve. This pain became disabling, but the diagnosis of sciatica proved incorrect. Pains in the left side of the back, fever, urobilinuria and other signs suggested cholecystitis and perhaps a complicating pancreatitis. Removal of a diseased gallbladder completely counteracted the symptoms.

Low Spinal Cord Injuries Following Spinal Anesthesia. E. Schildt. —p. 101.

Diaphragmatic Hernia.—Candolin reviews observations on 8 cases of diaphragmatic hernia. In 4 cases the hernia resulted from perforating trauma, in 1 from blunt trauma; there was 1 hiatus hernia and 2 cases were congenital. In 1 of the 4 cases in which incarceration existed it developed in connection with a pregnancy in the fourth month. In this woman the hernial sac filled the whole of the left part of the thorax and contained half the stomach, all of the small intestine, the major portion of the large intestine and the pancreas. Five patients were operated on by the abdominal route (2 died), 1 by the thoracic approach (died); 2 were not operated on (1 died from incarceration). The author believes that the transabdominal approach is less difficult than one might imagine. Operation should be performed during the sympto

Book Notices

Clinical Hematology. By Maxwell M. Wintrobe, M.D., Ph.D., Professor of Medicine, University of Utah School of Medicine, Salt Lake City, Utah. Second edition. Cloth. Price, $11. Pp. 862, with 211 illustrations. Lea & Febiger, South Washington Square, Philadelphia 6, 1946.

The first edition was one of the most comprehensive and authoritative textbooks on clinical hematology and the second edition justly maintains that distinction. The new edition includes practically every significant advance in hematology since the first edition was printed, as well as the addition of new illustrations and diagrams that add to the clarity of the text. Current material on folic acid, the Rh factor, nitrogen mustards, radioactive phosphorus, mineral and porphyrin metabolism, factors concerned with erythropoiesis and erythrocyte destruction, thiouracil and the newer hemostatic agents are some of the additions. These subjects will especially interest the prospective purchaser, but practically every chapter has been revised or modified to conform with the most current and accepted concepts. The author's ability as a teacher, clinician and investigator is reflected throughout, and many involved and controversial phases of hematology are presented in a concise, objective and lucid manner. Because of the careful editing, the book covers a range of subject matter that one would expect to find only in a larger treatise of several volumes. The extensive bibliography at the end of each chapter is painstakingly selected, as are the illustrations and diagrams. The author has wisely chosen to discuss diagnostic laboratory procedures in the appropriate section in each part of the book and has reserved for a separate chapter on methods only those procedures which could not be logically discussed in the appropriate chapter. This is a unique departure from most books on hematology but was done with the conviction that a laboratory procedure must have a background of understanding if it is to be intelligently applied and properly evaluated. The tests discussed are for the most part simple procedures which have been selected on the basis of their use in the doctor's office. A complete review of the contents of the entire book is not possible, but the student or physician may purchase this book with the conviction that he is buying one of the most comprehensive, current and authoritative textbooks on hematology available in any language.

Further Studies in Encephalography. By E. Graeme Robertson, M.D., F.R.C.P., F.R.A.C.P., Neurologist, Royal Melbourne Hospital, Melbourne. Cloth. Pp. 104, with 53 illustrations. Hafner Publishing Co., Inc., 31 E. 10th St., New York 3; Macmillan & Co., Ltd., 32-34 Flinders St., Melbourne, C 1, 1946.

The author discusses pressure gradients and the flow of cerebrospinal fluid and gas during their interchange in encephalography. In vivo observations are substantiated by painstaking in vitro experiments. For example it appears that, when the head is flexed, inflow of gas into the ventricular system is due to the outflow of fluid from the cerebral subarachnoid spaces, which allows expansion of the cerebral hemispheres, thus permitting inflow of gas into the ventricles. Indeed, by properly posturing the head it is possible to fill either the subarachnoid spaces or the ventricles with gas.

When the head is flexed 8[illegible] to 90 degrees gas usually enters the fourth ventricle and the aqueduct of Sylvius, which is a useful method of demonstrating lesions affecting these structures. A simple pendulum attached to a celluloid protractor determines the desired angle of flexion. The base line of the protractor is taped along the orbitomeatal base line of Reid.

The technic of encephalography includes a description of special charts, the use of two needles simultaneously (the lower needle being attached to a water manometer so that constant pressure may be maintained throughout the procedure), the advantages of oxygen and the slow introduction of gas and the choice of anesthesia. When local procaine alone is not feasible, tribromoethanol or paraldehyde by rectum, ether or intravenous sodium pentothal may be employed. The author gives the usual warning against the use of sodium pentothal in children but does not stress the necessity of an airway in case of laryngeal spasm.

The significance of films reproduced in the text is clearly explained by accompanying diagrams, especially in the chapter on brain stem lesions, which is particularly illuminating. Attention is drawn to the fact that shift of the falx cerebri is often helpful in lateralizing a brain tumor, especially of the temporal lobe. Pertinent observations are made regarding encephalography in cerebral atrophy and hydrocephalus, though these subjects are not dealt with as fully as they might be. Finally, the author states that encephalography may be used in the presence of increased intracranial pressure, and for the localization of posterior fossa as well as supratentorial tumors. With this opinion we cannot agree.

This is an excellent, though in some respects incomplete, treatise on the subject of encephalography that can be recommended without hesitation to every one interested in the subject.

Human Torulosis: A Clinical, Pathological and Microbiological Study with a Report of Thirteen Cases. By Leonard B. Cox, M.D., M.R.C.P., F.R.A.C.P., Consultant in Neurology to the Royal Australian Air Force, and Jean C. Tolhurst, M.Sc., Senior Bacteriologist to the Alfred Hospital, Melbourne, Australia. Cloth. Price, 25s. Pp. 149, with 67 illustrations. Melbourne: Melbourne University Press, in association with Oxford University Press, Melbourne and London. 1946.

The authors present a detailed study of 13 proved cases of torulosis, 8 of which came to postmortem examination. Combined with the discussion of their own cases are numerous illustrative excerpts from articles in United States, English, South African and Australian medical journals in which there have been reported some 120 cases of the disease. These are documented by a bibliography of 134 references.

The presentation of the subject is divided into ten sections. The first is devoted to historical background, the second to detailed discussion of the clinical and pathologic findings, and the remaining ones to the infection in the various physiologic systems, the microbiology of the causative organisms, torulosis of experimental animals, the detailed pathology of the disease, laboratory diagnosis, sources and routes of infection, treatment, summary and conclusions. The authors believe that the disease is more common than reports in the literature would indicate. In the majority of cases it takes the form of a meningitis or meningoencephalitis, febrile or afebrile and chronic or subacute. They demonstrated torula infection of the lungs in 5 of their fatal cases, a higher incidence than is reported elsewhere in the literature of the disease. They also point out that in over 15 per cent of cases lymphadenopathy occurs but seldom with demonstrable invasion of the lymph nodes by Torula histolytica. The occasional occurrence of Hodgkin's disease in chronic cases of torulosis leads them to believe that there is occasionally a direct etiologic relationship.

The illustrations include many excellent photographs of the gross lesions and excellent photomicrographs of the histologic pathology and of the various forms of the organism in culture. Torulosis, a systemic fungous infection caused by Cryptococcus neoformans (Torula histolytica), is likewise known as European blastomycosis or Busse-Buschke's disease. While it is still relatively uncommon, it has a wide geographic distribution, and numbers of cases have been reported in the Eastern and the Southern United States. This monograph is a distinct addition to the literature on the mycoses and is especially valuable because of the detailed studies of the new cases reported and for the condensation of the literature of the disease and the appended bibliography.

Some Chapters in Cambridge Medical History. By Sir Walter Langdon-Brown. Cloth. Price, $1.75. Pp. 119. Cambridge University Press, Bentley House, 200 Euston Rd., London, N. W. 1; Macmillan Company, 60 Fifth Ave., New York 11, 1946.

"History is the shadow cast by a few great men." Around this central theme Sir Walter Langdon-Brown gives the story of the foundations and growth of the Cambridge School of Medicine in a series of essays; a second implied theme—tradition, continuity and quality—becomes evident as the figures of medical history of four hundred years pass in review. Chapter headings outline the record: John Caius and the revival of learning; William Gilbert and the dawn of experiment; Francis Glisson and the insurgent century; William Heberden and the age of reason; John Haviland and the beginning of reform; The great triumvirate (Paget, Humphry and Foster) and the rise of the medical school; Clifford Allbutt and the transition from the nineteenth century. Thus are presented some of the beginnings of British medicine, the seventeenth century of individual achievement, the eighteenth century of consolidation of gains in medical science and the nineteenth century of educational building. The limitations of the subject confine references to Cambridge men for the most part, except for an occasional migration to Oxford or where affairs of the Royal College of Physicians concerned Cambridge activities. One interested in *medical* history will find here a wealth of historical detail attractively told in beautifully turned English which would *meet* the ideals of Sir Clifford Allbutt himself.

Textbook of Medical Treatment. By Various Authors. Edited by D. M. Dunlop, B.A., M.D., F.R.C.P., *Professor of Therapeutics and Clinical* Medicine, University of Edinburgh, Edinburgh, L. S. P. Davidson, B.A., M.D., F.R.C.P., Professor of Medicine and Clinical Medicine, University of Edinburgh, Edinburgh, and J. W. McNee, D.S.O., D.Sc., M.D., Physician, H. M. the King in Scotland. With a foreword by A. J. Clark, B.A., M.D., D.P.H. Fourth edition. Cloth. Price, $8. Pp. 923, with 38 illustrations. William Wood & Co., Mount Royal and Guilford Aves., Baltimore 2, 1946.

This large manual treats therapeutics comprehensively. It should serve as an excellent textbook for students and general practitioners to amplify the treatment stated in the books on general medicine. The fourth edition is entirely rewritten and contains a splendid chapter on penicillin therapy. Various newer drugs, including thiouracil, are carefully evaluated. Emphasis is given to general management rather than to a mere enumeration of drugs. This should serve as a basis for rational and critical judgment of all therapeutic agents. Included are sections on the treatment of venereal and skin diseases, tropical medicine and an excellent chapter on psychosomatic medicine.

Howell's Textbook of Physiology. Edited by John F. Fulton, M.D., Sterling Professor of Physiology, Yale University School of Medicine, and others. Fifteenth edition. Cloth. Price, $8. Pp. 1,304, with 507 illustrations. W. B. Saunders Company, W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, 1946.

Since its first appearance in 1905 this has been a standard physiology textbook for medical students. Now, after forty-one years, it is no longer a one man book but has been largely rewritten by a Yale group of authors, many of whom are authorities in major fields of physiology. It is a readable, reliable and up to date textbook which follows the general organization of previous editions. However, its value would be greatly bolstered by (1) reduction of the section on the nervous system, which now occupies more than a third of the pages, (2) the addition of a chapter on the liver and of a separate section on the endocrines, of which only reproduction is at present seriously considered, (3) a grossly expanded consideration of the role of physiology in medicine and (4) the inclusion of a chapter on aviation physiology.

How to Live: Rules for Healthful Living Based on Modern Science. By Irving Fisher, Ph.D., LL.D., and Haven Emerson, M.D. Prepared in collaboration with the Hygiene Reference Board of the Life Extension Institute. Twenty-First edition. Fabrikoid. Price, $2.50. Pp. 354. Funk & Wagnalls Co., 153 E. 24th St., New York, 1946.

Since the first edition of this book was published, it has had general acceptance as a competent guide to personal hygiene. For the most part it follows accepted dicta but occasionally breaks over into faddism or personal prejudices. Its point of view on the use of tobacco is distinctly in that classification. It condemns also the use of caffeine and of coffee and presents "pros and cons" on meat which lean heavily on the "con" side. Discounting these prejudices, however, the book contains a vast amount of useful information about health and its maintenance, written in easily understandable language.

How Can We Teach About Sex? By Benjamin C. Gruenberg. Public Affairs Pamphlet No. 122. Paper. Price, 10 cents. Pp. 31, with 7 illustrations. Public Affairs Committee, Inc., 22 E. 38th St., New York 16, 1946.

This booklet, developed by a well known authority on sex education, is a condensation in brief and readable form on what doctors and educators have concluded in relation to teaching about sex. It tells parents and educators what to do and what not to do. It contains a reading list divided according to the interests of parents and teachers, young men and women of college age, high school boys and girls, and children. The booklet can well be recommended to interested parties, particularly parents, teachers and the discussion groups of men's, women's and civic organizations.

Penicillin in Neurology. By A. Earl Walker, M.D., Associate Professor of Neurological Surgery, The University of Chicago, Chicago, and Herbert C. Johnson, M.D., Resident Neurological Surgeon, The University of *Chicago. Cloth. Price, $5. Pp. 202, with 72 illustrations. Charles C* Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois, 1946

This little monograph will find a warm welcome and will be useful. Since the introduction of penicillin a few years ago the drug has become a most useful therapeutic agent in many neurologic diseases, while it has proved disappointing in others. The authors have prepared an extensive survey of the already voluminous literature. They have combined this with their own considerable experimental and clinical observations to write this clear, concise and useful monograph. They discuss the various methods of administering the drug, its toxicity to the central nervous system, its irritative effect when applied to the cerebral cortex and the resulting convulsions, and its use in the treatment of infections of the meninges, brain and skull and of syphilis of the nervous system. There is appended a brief chapter dealing with some other antibiotics, such as streptomycin, streptothricin, actinomycin and clavacin. Although the book is to be recommended for current use, it must soon become out of date in this field of intensive investigation and rapid progress.

An Introduction to Social Biology. By Alan Dale, B.Sc. Cloth. Price, 15s. Pp. 396, with 189 illustrations. William Heinemann, Ltd., 99 Great Russell St., London, W. C. 1, 1946.

This book was originally prepared as a guide to the teaching of students of high school age in Great Britain. It covers such topics as the evolution of man, reproduction, man's relation to his environment and his health, nutrition, the balance of nature and reasons for man's dominance over other animals. The book is so advanced in its discussions that it would seem to American readers far too advanced for other than students of college age. It would be particularly useful to students in the first year of medicine who have not had opportunity for a thorough grounding in biology. The author has studied a vast amount of recent literature in the fields of science and medicine. Hence the work would serve also to bring up to date the physician who has had little time for reading in fields correlated with medicine.

Allgemeine Neurosenlehre: Biologie, Psychoanalyse und Psychohygiene leibseelischer Störungen in 22 Vorlesungen. Von Prof. Dr. Rudolf Brun, Dozent für Neurologie und Neurobiologie an der Universität Zürich. Second edition. Cloth. Price, 32 Swiss francs. Pp. 518, with 6 illustrations, Benno Schwabe & Co , Klosterberg 27, Basel 10, 1946.

In the revisions for this edition Professor Rudolf Brun was helped considerably by Dr. Heinrich Meng, who at one time was a psychoanalyst in Frankfort on Main. The book represents twenty-two lectures on the "biology, psychoanalysis, mental hygiene and psychosomatic disturbances"; it has covered considerable territory and, of necessity, in a rather eclectic manner. Despite the fact that the book was published in 1946, it already gives the impression of being somewhat out of date because the major developments in psychoanalysis and psychiatry of the past two decades were taken but little into consideration.

Musical Sons of Aesculapius. By Willard Marmelszadt, M.D. Foreword by Victor Robinson, M.D. Cloth. Price, $3. Pp. 116, with illustrations. Froben Press, 4 St. Luke's Place, New York 14, 1946.

Some years have passed since Fielding Garrison wrote his essay on "Medical Men Who Have Loved Music." This book deals with physicians who were themselves musicians and brings forth many interesting facts as to the extent to which such physicians participated in the musical life of their communities. The volume refers to many contemporaneous doctors who are associated with medical orchestras, chamber music groups and some who are noted as composers and virtuosos.

Science Since 1500: A Short History of Mathematics, Physics, Chemistry, Biology. By H. T. Pledge, Librarian, Science Museum of London, London. *Cloth.* Price, $5. Pp. 357, with illustrations. The Philosophical Library, Inc., 15 E. 40th St., New York 16, 1947.

This book is offered as a short history of mathematics, physics, chemistry and biology. It is a reference work of great value but is certainly not easy reading for those who wish merely to be generally informed in the fields concerned. The illustrations are well chosen, and the index is so complete as to aid greatly the reference quality of the work.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

LUMBAR SYMPATHECTOMY FOR ARTERIOSCLEROSIS AND ULCERATION OF LEGS

To the Editor:—I would appreciate the present consensus on sympathectomies for the relief of pain and ulceration of the legs on patients suffering from arteriosclerosis of the extremities complicated by diabetes mellitus. One patient that I have in mind was benefited by a paravertebral nerve block. There was an increased warmth of the extremities both objectively and subjectively. What is the outlook if the patient is subjected to a sympathectomy?

M.D., Florida.

Answer.—Lumbar sympathectomy has given excellent results in the relief of pain and has also stimulated healing of leg ulcers in patients with arteriosclerosis of the lower extremities, with and without the complication of diabetes mellitus. The pain in such cases may be of two types: the cramplike pain of muscle ischemia and the aching and tenderness directly resulting from the ulcer.

The relief of the cramplike pains, usually induced by exercise and commonly felt in the calf and foot, as well as the deep seated aching which may follow the more intense pain, depends largely on the amount of vascular spasm present, especially in the collateral circulation. If the blood supply to the distal part of the extremity is increased when vasospasm is relieved by a paravertebral nerve block or the intravenous injection of tetraethylammonium bromide or chloride, it may be safely concluded that a sympathectomy will give satisfactory results. The actual increase in blood supply may be measured by an electrothermocouple or a plethysmograph, but the subjective sense of increased warmth and frequently the relief of pain are excellent criteria on which to judge the desirability of a sympathectomy. If increase in temperature or blood flow is not demonstrated after autonomic block, sympathectomy probably will not give relief of pain of either type.

The healing of chronic indolent leg ulcers following lumbar sympathectomy in properly selected cases has been gratifying. In many instances the relief of vascular spasm has been followed almost immediately with relief of local pain and improvement in the vascularity of the ulcer bed and periphery. Large ulcers may be healed more rapidly by skin grafting.

The urine should be made sugar free, either by suitable diet or with the addition of insulin, before a sympathectomy is performed. A bilateral lumbar sympathectomy is advisable for the majority of patients, even though pain or ulceration has appeared only in one leg, since such involvement may thereby be prevented in the other. The usual extraperitoneal approach to the lumbar ganglions has a low surgical risk, and the patient can be up in two or three days and returned home in a week.

The outlook in the specific case mentioned should be good following lumbar sympathectomy, since there was increased warmth following paravertebral nerve block.

EFFECTS OF PHILGAS EXPLOSION

To the Editor:—What is the effect of an explosion of Philgas on the bronchial tree? Philgas is a bottle gas generated from a liquid and without odor, used for steam and ovens. A chef and restaurant manager attributes his profuse and productive morning cough and difficulty in breathing to an explosion of this gas about two years ago. He was severely burned on both arms at this time. X-ray studies with lipiodol reveal moderately extensive bilateral lower lobe emphysema attributed to narrowing and stenosis of the bronchioles. The pleura is thickened on both sides. Sputum examinations are negative for tuberculosis. The Wassermann test was negative. Allergic history is negative.

M.D., New Jersey.

Answer.—The history of symptoms immediately after the explosion is not sufficient to warrant any definite statements. Explosions may cause small tears and hemorrhages in the bronchial tree, which might later develop into a chronic infection such as bronchitis or bronchiectasis. This should cause bloody sputum, however, shortly after the injury, and if this was not present in the case reported, the explosion most likely was not the cause of the present symptoms and findings. Philgas is propane to which a mercaptan has been added, making it definitely not odorless. There is nothing from the gas itself which would be a pulmonary irritant

POSTOPERATIVE VENOUS THROMBOSIS IN THE LEGS

To the Editor:—A month ago I was operated on for intractable duodenal hemorrhage. The operation was a subtotal gastrectomy. A penetrating ulcer in the first part of the duodenum was found. Spinal anesthesia was employed. My condition at the time of operation was poor, my hemoglobin after a transfusion being 60 per cent. I am 37 years old. I made an uneventful recovery until forty-eight hours after the operation, when during the administration of an intravenous glucose-saline solution I was seized with severe pains in both lower extremities, followed by a chill. The chill was attributed to pyrogens, but on the following day there was deep tenderness in both calves, particularly on the left side. This delayed my recovery and now, two weeks after leaving the hospital, my left leg is quite swollen and both legs are quite painful. The treatment in vogue here is Dicumarol to the exclusion of virtually everything else. I receive now 100 mg. every four days. Does phlebitis begin as early as the second day generally? Could Dicumarol given early enough have prevented my condition? (It was started three days after operation.) At no time have I had a rise of temperature attributable to the phlebitis. Is this usual? Does the application of hot fomentations expedite recovery? My surgeon claims that it does not. Is there any danger of embolism in my present state if I walk? To *recapitulate:* I do not have fever, I have tenderness, I have edema, there has never been any involvement of the saphenous veins, there is no redness or heat in the legs, I am getting Dicumarol. Is the edema likely to be permanent? When can I safely resume my professional duties?

M.D., Illinois.

Answer.—There can be little doubt that the inquirer had venous thrombosis in the calves of both legs, as there was tenderness which was followed by edema.

Venous thrombosis does not ordinarily occur as early as the second postoperative day but it can happen, as it obviously did in the case under consideration.

Venous thrombosis may or may not be associated with an increase in oral temperature. The absence of an increased oral temperature does not exclude the diagnosis of venous thrombosis.

Good evidence that the application of hot fomentations favors cessation of venous thrombosis is lacking, but it is a time honored procedure, probably because it lessens distress and, along with elevation of the extremities, seems to hasten the disappearance of edema.

There is substantial and acceptable evidence that venous thrombosis is prevented by the administration of Dicumarol (3-3′-methylene-bis-[4-hydroxycoumarin]). However, it could not safely be used in a case like this as early as the second postoperative day because of the danger of inducing hemorrhage. As venous thrombosis usually occurs after the fourth or fifth postoperative day, administration of Dicumarol to prevent venous thrombosis is ordinarily begun on the third or fourth postoperative day. There is no acceptable standard dose of Dicumarol. The amount administered depends wholly on the effect of the drug on the percentage of prothrombin in the blood, and it is necessary when giving Dicumarol to determine the percentage of prothrombin in the blood at daily intervals; in exceptional cases when Dicumarol is administered over a long period it may be possible to administer it satisfactorily with a determination of the prothrombin time every second or third day. In the treatment or prevention of venous thrombosis it is desirable that the percentage of prothrombin in the blood be maintained between 10 and 30. The usual procedure is to give 300 mg. of Dicumarol on the first day and subsequently to consider administration of it only after the report has been received relative to the value for prothrombin in the blood. Ordinarily Dicumarol is not given if the prothrombin percentage in the blood is less than 20, and 200 mg. is administered if the prothrombin percentage in the blood exceeds 20. In the treatment of acute postoperative venous thrombosis, administration of the drug is ordinarily discontinued after there has been satisfactory reduction of the prothrombin in the blood until the patient leaves the hospital. Experience indicates that there is no need to continue administration of Dicumarol beyond this period except in unusual cases.

As operation was performed a month ago in the case under consideration there seems little further need for Dicumarol. The prospect of pulmonary embolism is extremely small if not wholly nonexistent. The problem presented at this time is that of preventing manifestations of chronic venous insufficiency, and this can be accomplished by the application of an adequate support to the limb to prevent edema. If this can be accomplished by means of ordinary elastic bandages, that method is satisfactory; if the edema cannot be prevented by this method, the inquirer may try the best grade of elastic stocking. If this procedure does not control the edema, he may use a pure gum rubber bandage 3 inches wide and 15 feet long (Davol Rubber Company, Providence, R. I.). The support should be worn until edema does not occur when the support is discontinued. In about half of the instances the support can be discarded within a period of three or four months. In other instances it may be advisable to wear it indefinitely. Patients are instructed to discard the support for one day each month and to reapply it only if edema occurs.

There does not seem to be any reason why normal activity cannot be resumed.

TREATMENT OF HOOKWORM INFECTION

To the Editor:—A veteran contracted hookworm infection while serving in the Philippines. After six months of treatment with carbon tetrachloride, tetrachlorethylene and hexylresorcinol he still has symptoms and shows worms and ova in the stools. Is there anything new or any routine suggested for eradication of these helminths? *M. A. Polk, M.D., Chicago.*

Answer.—It is indeed a rare case of hookworm infection in which the proper use of carbon tetrachloride, tetrachlorethylene and hexylresorcinol fails to give relief. Although only about 80 per cent of the hookworms will be removed by hexylresorcinol in mass treatments of several thousand cases, it is usually possible to reduce the number of worms in any single individual below the dangerous level by the proper use of this drug. This substance can be taken in 1 Gm. doses and repeated the second day, or 2 Gm. may be taken in a single dose. The taking of a single gram of hexylresorcinol and the repetition of this two weeks later if necessary may reduce the number of worms present to less than 25, which is a number which will not produce symptoms. Precautions should be taken to see that the patient takes a light evening meal and that the hexylresorcinol is given to the patient in the morning without any breakfast. Although water may be taken in any amount, food should not be taken for at least four hours after giving the drug. This will prevent the hexylresorcinol reacting with the food and allow its maximum effect on the worm. It is well worth checking a patient who has reacted to such active drugs so poorly in order to know that he has actually taken the required amount at the proper time.

ELECTROLYTE RESORPTION BY RENAL TUBULES

To the Editor:—In Best and Taylor: Physiological Basis of Medical Practice (ed. 3, 1946, p. 639) the following statement is made: "The absorption of sodium is influenced by the adrenal cortex and the posterior pituitary. The hormone of the adrenal cortex is essential for the normal reabsorption of sodium. . . . The antidiuretic hormone of the pituitary exerts the opposite effect, inhibiting the absorption of sodium from the proximal tubule and increasing the reabsorption of water and chloride mainly from the distal tubule." I presume there is a misprint and that the sentence should read "increasing the reabsorption of water and decreasing the reabsorption of chloride." Is it true that sodium is lost with chloride or do both the pituitary and the adrenal conserve sodium?

Samuel L. Immerman, M.D., Philadelphia.

Answer.—The only well established hormonal influence on sodium resorption by the renal tubules is that known to be produced by the adrenal cortex. At present it cannot be stated definitely that the posterior pituitary has a specific effect on the resorption or excretion of either sodium or chloride. A slight but variable decrease in chloride resorption has been produced by the antidiuretic hormone. According to Pitts and Lotspeich (*Am. J. Physiol.* **147**:138, 1946) there is a reciprocal relation in the resorption of bicarbonate and chloride ions by the kidney tubules. Certainly many factors must be studied simultaneously before one would be in a position to conclude that a hormone directly affects the resorption of any ion from the tubules of the kidney. Most studies are lacking in a sufficiently complete characterization of the electrolyte pattern of the blood and urine at the time of studying the effect of any given glandular extract or deficiency state.

REPEATED SKIN INFECTIONS

To the Editor:—A woman develops skin infections following any trauma to the skin, such as minute punctures of the skin following cooking or washing. In a few days there is a local area of erythema which becomes infected and pustular. The condition heals without scar formation after three weeks. All laboratory tests and blood chemical studies have been negative. At the present time the patient is receiving a course of staphylococcus ambotoxoid. Are there other methods of increasing skin immunity for preventing infections of this type? Can staphylococcus ambotoxoid be bolstered by the adjuvant injection of liver extract or foreign protein injection? *M.D., New York.*

Answer.—It is presumed that the patient described in the query has had a physical examination and that nothing abnormal has been found. In addition, anemia, diabetes and diseases of the kidneys should be ruled out. Minimal changes may be present in the skin of the hands caused by excessive use of soap cleansers and water in the kitchen. There remains a group that is an easy prey to ordinary skin infections in whom all clinical and laboratory study proves fruitless for any clue which may be causative. Nonspecific measures such as the parenteral use of milk products and some of the metals, such as tin and manganese, occasionally yield brilliant results. This approach is being utilized now much less than formerly. Staphylococcus toxoid may be helpful. Recently the systematic and regular use of 70 per cent alcohol spongings of the skin has been advocated. A prolonged application of some well tolerated antisep is worth while. Daily soaks of the hands with aqueous potassium permanganate solution 1:5,000 or 1:7,000 may be helpf but stains the skin. Mercury bichloride may be used in streng of 1:5,000. Ointments such as 0.5 to 5 per cent ammoniated mercury have stood the best test of time. Ammoniated mercury may be irritating to a few. Furacin dressing is a proprietary ointment which is apparently an efficient remedy. The sulfonamides sensitize the skin too often to justify advocating their use locally, even though they are efficient. The internal use of these remedies should be reserved for some more serious occasions. Penicillin locally, while not as frequent a sensitizer as the sulfonamides, is proving to be such with seemingly increasing frequency. The use of ultraviolet rays in suberythema doses at regular intervals may be of decided benefit to patients who are easy victims of the simple staphyloccic infections.

DIPHTHERIA ANTITOXIN FOR NONDIPHTHERITIC PHARYNGITIS

To the Editor:—Is diphtheria antitoxin of therapeutic value in any disease besides diphtheria? A recent survey of the records of reported cases of diphtheria compared with records of diphtheria antitoxin supplied by the state department of health shows that antitoxin has been used in several cases in dosages of 20,000 to 40,000 units. When questioned, the doctors replied that it was their custom in practice to use diphtheria antitoxin if patients had "nasty" throats which did not respond to penicillin and sulfonamides. This usually produced a clinical improvement. Since diphtheria does not always produce the "typical membrane" and may be present when culture and smears are negative, should these cases that respond to antitoxin be diagnosed as diphtheria?

J. T. Millington, M.D., Wilkes-Barre, Pa.

Answer.—It is true that some severe inflammations of the throat subside following the administration of diphtheria antitoxin. However, this does not necessarily mean that the antitoxin was responsible for the improvement. Unless the condition present was actually diphtheria, although unconfirmed by laboratory diagnosis, it should not be assumed that the diphtheria antitoxin was accountable for the favorable action.

Many years ago, before diphtheria antitoxin was as highly refined and concentrated as at present, it was sometimes believed that diphtheria antitoxin was beneficial in certain inflammatory conditions of the throat not due to diphtheria. This was explained on the basis of a foreign protein reaction. But when diphtheria antitoxin is used for remedial purposes, a definite diagnosis of diphtheria should be established only by laboratory procedures. Even when the culture is positive for diphtheria it may be advisable to make a test for virulence.

WATERY SECRETION FROM NIPPLE

To the Editor:—A woman aged 55, who has been in good health except for a hysterectomy about five years ago for a fibroma of the uterus, recently noticed a watery secretion from her left nipple. The breast is normal in appearance and to palpation. Axillary or supraclavicular glands are not palpable. The kidney is normal. The blood pressure is 150/90. She is extremely frightened from reading about precancerous conditions in lay papers. I know of milk and watery secretions from the breasts of children, both girls and boys, and I consider this condition of no consequence. Am I wrong? Would you suggest that I give her glandular therapy, and if so would it be estrogen or androgen?

Simon Steinbach, M.D., New York.

Answer.—Watery secretion from the nipple of the breast as described may be due to irritation of the nipple or to stimulation of the ducts themselves. If an intraductal papilloma or intraductal carcinoma was present the secretion should be dark or blood tinged. As this is not the case, one would be justified in carefully observing the patient at frequent intervals. If at any time a thickening of one of the ducts is found or the character of the secretion is altered, simple mastectomy would be preferable to cannulating the ducts in an attempt to dissect out the one under suspicion. Glandular treatment would be contraindicated, as the stimulation of the estrogens might be aggravating and androgen therapy could mask the symptoms. X-ray treatments have proved satisfactory in drying up such secretion.

CLIMATE FOR BRONCHITIS

To the Editor:—What is the present opinion regarding the effect of climate on chronic bronchitis in a child 2 years old? Would a mild dry climate or a mild moist climate be better? A 2 year old girl has mild chronic bronchitis characterized by frequent severe attacks of acute bronchitis. Would the Gulf Coast or central Texas be better? *Lieutenant, M. C., A. U. S.*

Answer.—A mild dry climate is best for a child with chronic bronchitis. The climate of central Texas would be much preferable to that of the Gulf Coast.
